# Foreword

When the author of this book, Dirk Strauss, asked me if I'd write a foreword, it took me about n milliseconds (where n is a small integer) to reply with a "yes". I've known Dirk for a few years, starting when we worked on a project that involved C# Code Contracts. Quite some time ago I worked with the Research in Software Engineering group at Microsoft Research, who originally developed Code Contracts, so when I saw Dirk's explanation of the technology, I knew immediately that Dirk has a rare ability to understand, use, and most importantly with regards to *C# 7 and .NET Core Cookbook*, explain ideas in a clear and precise way.

Most of my colleagues and I believe that a major challenge facing .NET developers, and in fact all software developers, is the astonishing explosion of new technologies and the associated tidal wave of various forms of documentation. It's becoming increasingly difficult to find those few valuable resources that get to the point quickly, and explain technologies and paradigms succinctly so you can get on with your work. This book is one such reference. I hope you'll enjoy and value *C# 7 and .NET Core Cookbook* as much as I do!

**Dr. James McCaffrey**

Microsoft Research

# About the Author

**Dirk Strauss** is a software developer and Microsoft .NET MVP from South Africa with over 13 years of programming experience. He has extensive experience in SYSPRO Customization (an ERP system), with C# and web development being his main focus.

He works for Evolution Software, but in all fairness, he can't really call it working at all. When you're having fun and loving what you do with incredibly inspirational individuals, you will not work a day in your life.

He authored the *C# Programming Cookbook* in 2016 (also published by Packt) and has written for Syncfusion, contributing to the Succinctly series of eBooks.

He also blogs at <https://dirkstrauss.com/>, whenever he gets a chance.

*I would like to thank the team at Evolution Software for being such an incredible source of inspiration to me in my professional and personal life. Working with you folks challenges me to become better at what I do and the way I live my life. Being a part of the Evolution Software team is the most fulfilling experience of my career. It is something that I will always be incredibly grateful for.*

*Last but by no means least, I would like to thank my wife and kids. Thank you for reminding me what life is actually about. Without your love and support, this book would not have been possible. I love you.*

# About the Reviewer

**Fabio Claudio Ferracchiati** is a senior consultant and a senior analyst/developer using Microsoft technologies. He works for Agic Technology (<http://www.agictech.com>). He is a Microsoft Certified Solution Developer for .NET, Microsoft Certified Application Developer for .NET, and Microsoft Certified Professional. He is also a prolific author and a technical reviewer. Over the last ten years, he's written articles for Italian and international magazines, and coauthored more than 10 books on a variety of computer topics.

How to do it...

How it works...

Using AWS and S3

Getting ready

How to do it...

How it works...

# Creating C# Lambda functions with AWS

## Getting ready

How to do it...

How it works...

# Preface

Visual Studio 2017 allows developers to harness the latest technology and create world-class applications across a variety of platforms. The new language features in C# 7.0 are powerful tools that will allow you to write better functioning software and deliver complex business requirements quicker.

The book takes a look at all of the awesome new features in C# 7. It also looks at how developers can write diagnostic analyzers to produce better code and adhere to specific code standards. It explores .NET Core 1.1 and looks at creating an ASP.NET Core application using the MVC framework.

If creating mobile apps is something you are interested in, this book will show you how to do so using Cordova. If you want to create native iOS applications, this book shows you how to do just that using Visual Studio for Mac.

If serverless computing is something that want to understand more, then look no further. In the book, we take a look at what the term serverless computing means. We also look at how to create an Azure function and how to use AWS and S3. Lastly, hot off the press from Amazon, we take a look at using C# lambda functions with AWS.

This book will show you the beauty of C#, which when combined with the power of Visual Studio, makes you a very formidable developer, capable of meeting a variety of programming challenges head on.

Whatever your skill level when it comes to programming with C#, this book provides something for everyone and will make you a better developer.

# What this book covers

[Chapter 1](#), *New Features in C# 7.0*, shows how C# 7.0 brings a lot of new functionality to the C# language. The biggest of these features by far are Tuples and pattern matching. Getting to grips with what's new in C# 7.0 is essential for developers in order to stay on top of their game.

[Chapter 2](#), *Classes and Generics*, form the building blocks of software development and are essential in building good code. The power of classes, which is to describe the world around us and translate it into a programming language that a compiler can understand, allows developers to create great software.

[Chapter 3](#), *Object-Oriented Programming in C#*, is the foundation of C# and object-oriented programming (OOP). Understanding this concept is essential to .NET developers everywhere.

[Chapter 4](#), *Code Analyzers in Visual Studio*, talks about how code analyzers help developers to write better code. Be sure that the code you or your team ships measures up to your specific set of code quality standards.

[Chapter 5](#), *Regular Expressions*, is about how regex make use of patterns that describe a string through the use of special characters that denote a specific bit of text to match. The use of regex, when applied properly, can be a very powerful approach to certain programming problems.

[Chapter 6](#), *Working with Files, Streams, and Serialization*, teaches the readers that working with files, streams, and serialization is something you as a developer will do many times. Being able to do so correctly will definitely give you an edge as a developer.

[Chapter 7](#), *Making Apps Responsive with Asynchronous Programming*, talks about how asynchronous programming is an exciting feature in C#. It allows you to continue program execution on the main thread while a long-running task finishes its execution. This enables your applications to remain responsive.

[Chapter 8](#), *High Performance Programming Using Parallel and Multithreading in C#*, improves your code's performance. Using multithreading and parallel programming can mean the difference between users experiencing an application as working or broken.

[Chapter 9](#), *Composing Event-Based Programs Using Reactive Extensions*, teaches the reader how Rx is an exciting technology. If you need to create search-as-you-type functionality in an application, have data that changes notify your application instead of having to poll the data all the time (think stock prices), or generally make your app more responsive, the chances are you need to consider using Rx.

[Chapter 10](#), *Exploring .NET Core 1.1*, is about the buzz regarding .NET Core these days. It allows you to create cross-platform applications that run on Windows, Linux, and macOS. Knowing how to use it is essential for all .NET developers.

[Chapter 11](#), *ASP.NET Core on the MVC Framework*, talks about the MVC framework, which is named according to the MVC design pattern it follows. It allows developers to separate the logic by letting each component of the framework focus on one specific thing. It is this separation of concerns that makes MVC

so powerful, especially when combined with .NET Core.

[Chapter 12](#), *Choosing and Using a Source Control Strategy*, is about how source control is an essential part of every developer's toolkit. It doesn't matter whether you are a hobbyist or professional programmer; when you get up from your desk to go home, you'd better be sure your code is safe.

[Chapter 13](#), *Creating a Mobile Application in Visual Studio*, allows developers to create mobile applications with ease. It also gives developers more choice about how to go about doing it. From creating a mobile app with Xamarin, to using Cordova, to writing native iOS applications with Visual Studio for Mac, .NET developers can expand their service offering using the IDE they know and love.

[Chapter 14](#), *Writing Secure Code and Debugging in Visual Studio*, talks about how debugging is something developers do more often than not. Being able to do so efficiently is a different story. In a similar way, being able to write secure code is essential to any developer. Creating secure code and being able to efficiently debug that code properly results in a better end product.

[Chapter 15](#), *Creating Microservices on Azure Service Fabric*, is about how, traditionally, developers wrote applications in a monolithic manner, which is one single executable broken up into components via classes and so on. Microservices is a technology that aims to address the issues surrounding traditional monolithic applications. It allows developers to create smaller bits (services) that can function on their own without being dependent on any of the other services.

[Chapter 16](#), *Azure and Serverless Computing*, is about how serverless does not mean the lack of a server, but rather you (or the application) does not know which server is used to provide some functionality to an application. Splitting some of your application logic into a serverless-type architecture allows for extreme scalability when loads increase (or decrease), increased performance, and less code to write and debug.

# **What you need for this book**

You will need the latest version of Visual Studio 2017. For some of the chapters on mobile development, you will need an active Apple iTunes account. Regarding the last chapter, you will need to create a free AWS account. Lastly, some of the recipes might also require access to the Azure portal.

# **Who this book is for**

The book will appeal to C# and .NET developers who have a basic familiarity with C# and the Visual Studio 2015 environment.

# Sections

In this book, you will find several headings that appear frequently (Getting ready, How to do it, How it works, There's more, and See also).

To give clear instructions on how to complete a recipe, we use these sections as follows:

# Getting ready

This section tells you what to expect in the recipe, and describes how to set up any software or any preliminary settings required for the recipe.

# **How to do it...**

This section contains the steps required to follow the recipe.

# **How it works...**

This section usually consists of a detailed explanation of what happened in the previous section.

# **There's more...**

This section consists of additional information about the recipe in order to make the reader more knowledgeable about the recipe.

## See also

This section provides helpful links to other useful information for the recipe.

# Conventions

In this book, you will find a number of text styles that distinguish between different kinds of information. Here are some examples of these styles and an explanation of their meaning.

Code words in text, database table names, folder names, filenames, file extensions, pathnames, dummy URLs, user input, and Twitter handles are shown as follows: "You will find the script in the `_database scripts` folder in the accompanying source code."

```
public override void Initialize(AnalysisContext context)
{
    context.RegisterSymbolAction>AnalyzeSymbol,
    SymbolKind.NamedType);
}
```

**New terms** and **important words** are shown in bold. Words that you see on the screen, for example, in menus or dialog boxes, appear in the text like this: "From the Tools menu, select NuGet Package Manager and then Manage NuGet Packages for Solution...."

*Warnings or important notes appear in a box like this.*

*Tips and tricks appear like this.*

# Reader feedback

Feedback from our readers is always welcome. Let us know what you think about this book-what you liked or disliked. Reader feedback is important for us as it helps us develop titles that you will really get the most out of.

To send us general feedback, simply e-mail [feedback@packtpub.com](mailto:feedback@packtpub.com), and mention the book's title in the subject of your message.

If there is a topic that you have expertise in and you are interested in either writing or contributing to a book, see our author guide at [www.packtpub.com/authors](http://www.packtpub.com/authors).

# **Customer support**

Now that you are the proud owner of a Packt book, we have a number of things to help you to get the most from your purchase.

# Downloading the example code

You can download the example code files for this book from your account at <http://www.packtpub.com>. If you purchased this book elsewhere, you can visit <http://www.packtpub.com/support> and register to have the files e-mailed directly to you.

You can download the code files by following these steps:

1. Log in or register to our website using your e-mail address and password.
2. Hover the mouse pointer on the SUPPORT tab at the top.
3. Click on Code Downloads & Errata.
4. Enter the name of the book in the Search box.
5. Select the book for which you're looking to download the code files.
6. Choose from the drop-down menu where you purchased this book from.
7. Click on Code Download.

You can also download the code files by clicking on the Code Files button on the book's webpage at the Packt Publishing website. This page can be accessed by entering the book's name in the Search box. Please note that you need to be logged in to your Packt account.

Once the file is downloaded, please make sure that you unzip or extract the folder using the latest version of:

- WinRAR / 7-Zip for Windows
- Zipeg / iZip / UnRarX for Mac
- 7-Zip / PeaZip for Linux

The code bundle for the book is also hosted on GitHub at <https://github.com/PacktPublishing/CSharp-7-and-DotNET-Core-Cookbook>. We also have other code bundles from our rich catalog of books and videos available at <https://github.com/PacktPublishing/>. Check them out!

# Errata

Although we have taken every care to ensure the accuracy of our content, mistakes do happen. If you find a mistake in one of our books-maybe a mistake in the text or the code-we would be grateful if you could report this to us. By doing so, you can save other readers from frustration and help us improve subsequent versions of this book. If you find any errata, please report them by visiting <http://www.packtpub.com/submit-errata>, selecting your book, clicking on the Errata Submission Form link, and entering the details of your errata. Once your errata are verified, your submission will be accepted and the errata will be uploaded to our website or added to any list of existing errata under the Errata section of that title.

To view the previously submitted errata, go to <https://www.packtpub.com/books/content/support> and enter the name of the book in the search field. The required information will appear under the Errata section.

# Piracy

Piracy of copyrighted material on the Internet is an ongoing problem across all media. At Packt, we take the protection of our copyright and licenses very seriously. If you come across any illegal copies of our works in any form on the Internet, please provide us with the location address or website name immediately so that we can pursue a remedy.

Please contact us at [copyright@packtpub.com](mailto:copyright@packtpub.com) with a link to the suspected pirated material.

We appreciate your help in protecting our authors and our ability to bring you valuable content.

# Questions

If you have a problem with any aspect of this book, you can contact us at [questions@packtpub.com](mailto:questions@packtpub.com), and we will do our best to address the problem.

# New Features in C# 7.0

In this first chapter, we will take a look at the C# 7.0 features by covering them in the following recipes:

- Working with Tuples - getting started
- Working with Tuples - going deeper
- Pattern matching
- Out variables
- Deconstruction
- Local functions
- Improvements to literals
- Ref returns and locals
- Generalized async return types
- Expression bodies for accessors, constructors, and finalizers
- throw expressions

# Introduction

C# 7.0 brings a lot of new functionality to the C# language. If you were left wanting more after the release of C# 6.0, then C# 7.0 will not disappoint you at all. It focuses on consuming data, simplifying code, and improving performance. Mads Torgersen who is the C# Program Manager noted that C# 7.0's biggest feature by far is **Tuples**. The other is **pattern matching**. These two features (as well as the others) were met with enthusiasm from C# developers worldwide. It is, therefore, no guess that developers will immediately start implementing these new features introduced in C# 7.0. It will, therefore, be very beneficial to get to grips with what C# 7.0 has to offer and implement the new language features in your development projects as soon as possible.

Throughout this book, I will be using the release candidate of Visual Studio 2017. Some features and methods of doing things might change between the time of writing and the final release of Visual Studio 2017.

# Working with Tuples - getting started

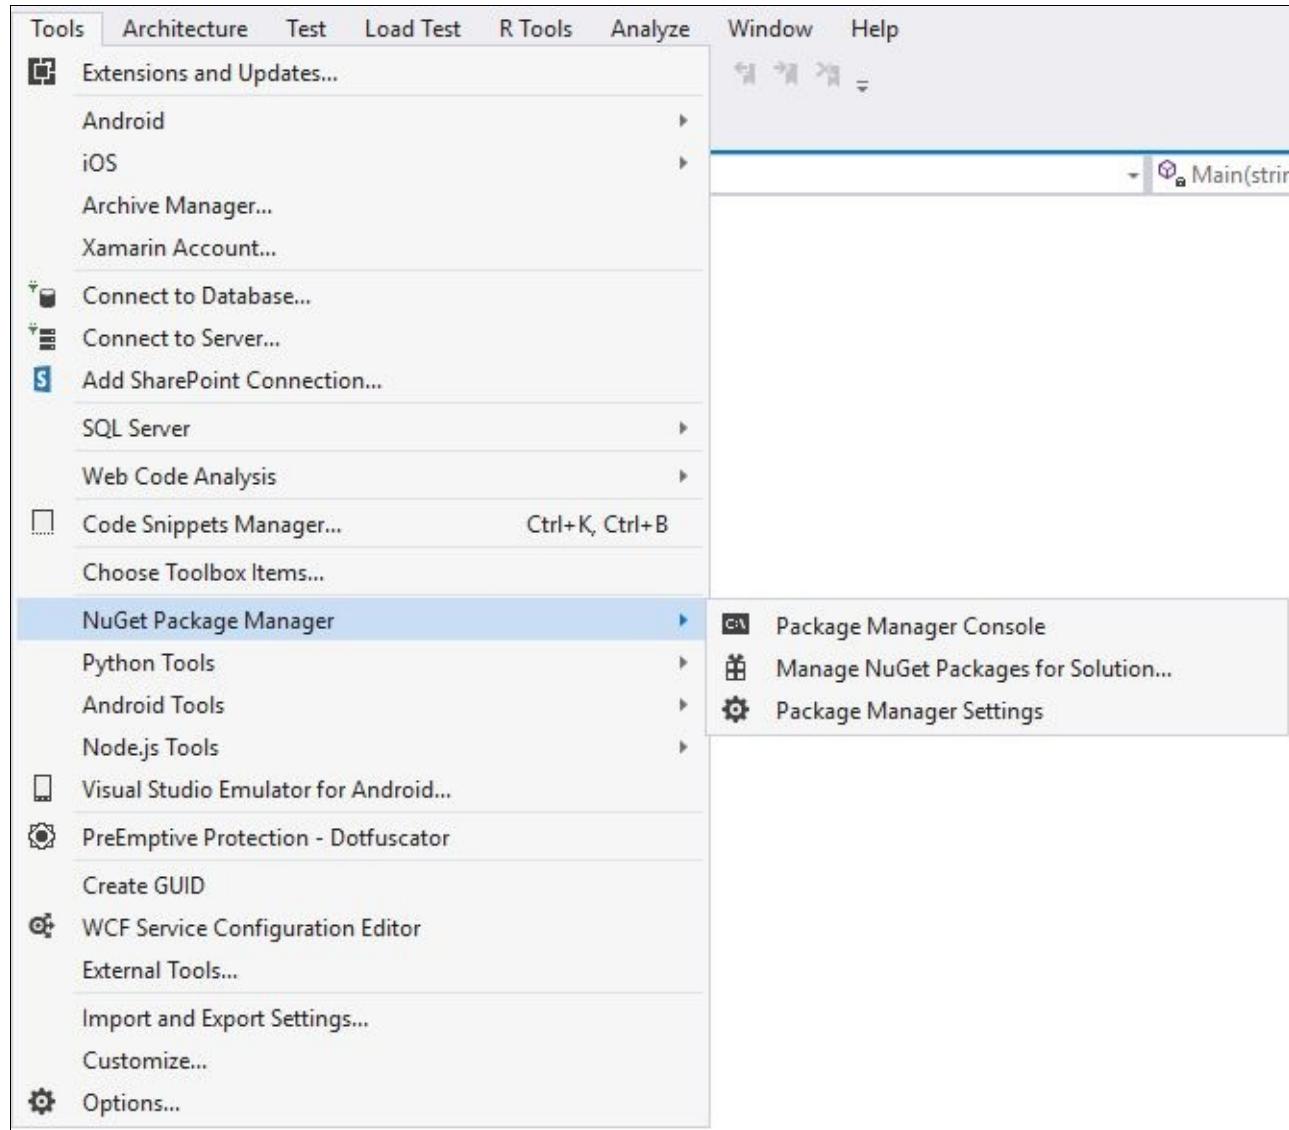

I have come across many instances where I wanted to return more than one value from a method. As Mads Torgersen pointed out, the existing options available to developers are not optimal. C# 7.0 has, therefore, introduced **Tuple types** and **Tuple literals** to allow developers an easy way of returning multiple values from methods. Developers can also rest easy when creating Tuples. Tuples are structs, which are value types. This means that they are created locally and are passed by copying the contents. Tuples are also mutable and Tuple elements are public mutable fields. I am personally very excited about using Tuples. Let's explore Tuples in closer detail in the following recipe.

# Getting ready

Start off by creating a regular console application in Visual Studio 2017. Simply call the project you create cookbook. Before I can jump into using Tuples in C# 7.0, I need to add in a NuGet package. Bear in mind that I am using the release candidate of Visual Studio. This process might change between now and the final release of the product.

1. To do this, head on over to Tools, NuGet Package Manager and then, click on Manage NuGet Packages for Solution....

2. Select the Browse tab and type in `ValueTuple` in the search box. The `System.ValueTuple` by Microsoft NuGet package should be displayed. Select the cookbook project under Manage Packages for Solution and click on the Install button.

*Take note that I am using Visual Studio 2017 RC while writing portions of this book. You probably will not need to add `System.ValueTuple` from NuGet some time in the future after the final release. Adding `System.ValueTuple` from NuGet might, however, remain a requirement. Only time will tell.*

Installed: [not installed](#)[Uninstall](#)Version: [Latest stable 4.3.0](#)[Install](#)**Options****Description**

Provides the System.ValueTuple structs, which implement the underlying types for C# 7 tuples.

Each package is licensed to you by its owner. NuGet is not responsible for, nor does it grant any licenses to, third-party packages.

 Do not show this again

- Visual Studio will now show you a prompt to review the changes you are about to make to your project. Just click on the OK button. Lastly, you will need to provide the License Agreement required by Microsoft. Just click on the I Accept button. Visual Studio will now start the NuGet package installation. It will show you its progress in the Output window.

```

After all this is complete, my Visual Studio solution looks as follows:

You will now be ready to create your first method that works with Tuples. Let's see how to do that next.

```
namespace cookbook<br/> {<br/> class Program<br/> {<br/> static void Main(string[] args)<br/> {<br/><br/> }<br/><br/> public class Chapter1<br/> {<br/><br/> }<br/> }

static void Main(string[] args)<br/> {<br/> int[] scores = { 17, 46, 39, 62, 81, 79, 52, 24 };<br/> Chapter1 ch1 = new Chapter1();<br/> var s = ch1.GetAverageAndCount(scores);<br/> }

public (int, int) GetAverageAndCount(int[] scores)<br/> {<br/><br/> }

public (int, int) GetAverageAndCount(int[] scores)<br/> {<br/> var returnTuple = (0, 0);<br/> return returnTuple;<br/> }

static void Main(string[] args)<br/> {<br/> int[] scores = { 17, 46, 39, 62, 81, 79, 52, 24 };<br/> Chapter1 ch1 = new Chapter1();<br/> var s = ch1.GetAverageAndCount(scores);<br/> WriteLine($"Average was {s.Item1} across {s.Item2} students");<br/> ReadLine();<br/> }

using static System.Console;

public (int average, int studentCount) <br/> GetAverageAndCount(int[] scores)<br/> {<br/> var returnTuple = (0, 0);<br/> return returnTuple;<br/> }

static void Main(string[] args)<br/> {<br/> int[] scores = { 17, 46, 39, 62, 81, 79, 52, 24 };<br/> Chapter1 ch1 = new Chapter1();<br/> var s = ch1.GetAverageAndCount(scores);<br/> WriteLine($"Average was {s.average} across {<br/> s.studentCount} students");<br/> ReadLine();<br/> }

var returnTuple = (0, 0);

var returnTuple = (ave:0, sCount:0);

public (int average, int studentCount) <br/> GetAverageAndCount(int[] scores)<br/> {<br/> var returnTuple = (ave:0, sCount:0);<br/> return returnTuple;<br/> }
```

Tuples play really nicely together. As long as the Tuple types match up, you do not have to worry that the ave and sCount names in the Tuple literal don't match the average and studentCount names of the return type.

# How it works...

So far in this recipe, we have seen that Tuples give developers a lot of flexibility when you need to return several values from a method. While the dummy implementation of `GetAverageAndCount()` simply returns the zero-valued Tuple literal, it gives you some idea how Tuples are *wired up*. This recipe is the foundation for the next recipe. I encourage you to go through both recipes thoroughly in order to gain the full benefit from understanding Tuples and how to use them.

# Working with Tuples - going deeper

I will now start adding more meat to the dummy implementation of the `GetAverageAndCount()` method we created in the previous recipe. If you are new to Tuples, and have not worked through the previous recipe, I encourage you to do so first before starting to work through this recipe.

# Getting ready

You need to have completed the code steps in the recipe *Working with Tuples - getting started*, in order to work through this recipe. Ensure that you have added the required NuGet package as specified in the previous recipe.

```
var s = ch1.GetAverageAndCount(scores);
```

```
var (average, studentCount) = ch1.GetAverageAndCount(scores);
```

```
WriteLine($"Average was {average} across {studentCount} students");
```

```
static void Main(string[] args)<br/> {<br/> int[] scores = { 17, 46, 39, 62, 81, 79, 52, 24 };<br/> Chapter1 ch1 = new Chapter1();<br/> var (average, studentCount) = ch1.GetAverageAndCount(scores);<br/> WriteLine($"Average was {average} across {<br/> studentCount} students");<br/> ReadLine();<br/> }
```

```
public (int average, int studentCount) <br/> GetAverageAndCount(int[] scores)<br/> {<br/> var returnTuple = (ave:0, sCount:0);<br/> return returnTuple;<br/> }
```

```
using System.Linq;
```

```
public (int average, int studentCount) <br/> GetAverageAndCount(int[] scores)<br/> {<br/> var returnTuple = (ave:0, sCount:0);<br/> return Tuple.Create(returnTuple.ave = scores.Sum() / scores.Count(),<br/> return Tuple.Create(returnTuple.sCount = scores.Count()));<br/> return returnTuple;<br/> }
```

```
return Tuple.Create(returnTuple.ave = scores.Sum() / scores.Count(),<br/> return Tuple.Create(returnTuple.sCount = scores.Count()));
```

```
public (int average, int studentCount)<br/> GetAverageAndCount(int[] scores)<br/> {<br/> var returnTuple = (ave:0, sCount:0);<br/> return Tuple.Create((scores.Sum() / scores.Count()), scores.Count());<br/> return returnTuple;<br/> }
```

```
public static class ExtensionMethods<br/> {<br/><br/> }
```

```
public static bool CheckIfBelowAverage(<br/> this int classAverage, int threshold)<br/> {<br/> if (classAverage < threshold)<br/> {<br/> // Notify head of department<br/> return true;<br/> }<br/> else<br/> return false;<br/> }
```

```
public (int average, int studentCount, bool belowAverage) <br/> GetAverageAndCount(int[] scores, int threshold)<br/> {<br/><br/> }
```

```
var returnTuple = (ave: 0, sCount: 0, subAve: true);
```

```
returnTuple = (scores.Sum() / scores.Count(), scores.Count(),<br/> return Tuple.Create(returnTuple.ave.CheckIfBelowAverage(threshold)));
```

```
public (int average, int studentCount, bool belowAverage) <br/>
GetAverageAndCount(int[] scores, int threshold) <br/> { <br/> var returnTuple = (ave: 0,
sCount: 0, subAve: true); <br/> returnTuple = (scores.Sum() / scores.Count(),
scores.Count(), <br/> returnTuple.ave.CheckIfBelowAverage(threshold)); <br/> return
returnTuple; <br/> }

int threshold = 51; <br/> var (average, studentCount, belowAverage) =
ch1.GetAverageAndCount(<br/> scores, threshold);

WriteLine($"Average was {average} across {studentCount}<br/> students. {(average <
threshold ? <br/> " Class score below average." : <br/> " Class score above average.")}");
```

```
static void Main(string[] args) <br/> { <br/> int[] scores = { 17, 46, 39, 62, 81, 79, 52, 24 }; <br/>
Chapter1 ch1 = new Chapter1(); <br/> int threshold = 51; <br/> var (average,
studentCount, belowAverage) = <br/> ch1.GetAverageAndCount(scores, threshold); <br/>
WriteLine($"Average was {average} across {studentCount} <br/> students. {(average <
threshold ? <br/> " Class score below average." : <br/> " Class score above average.")}"); <br/>
ReadLine(); <br/> }
```

```
int threshold = 40;
```

```
int[] scores = { 17, 46, 39, 62, 81, 79, 52, 24 };
```

```
int[] scores = { 17, 46, 39, 62, 81, 79, 52, 24, 49 };
```

```
public static bool CheckIfBelowAverage(<br/> this double classAverage, int threshold)
<br/> { <br/> <br/> }
```

```
public (double average, int studentCount, bool belowAverage) <br/>
GetAverageAndCount(int[] scores, int threshold) <br/> { <br/> <br/> }
```

```
var returnTuple = (ave: 0D, sCount: 0, subAve: true);
```

```
returnTuple = ((double)scores.Sum() / scores.Count(), <br/> scores.Count(), <br/>
returnTuple.ave.CheckIfBelowAverage(threshold));
```

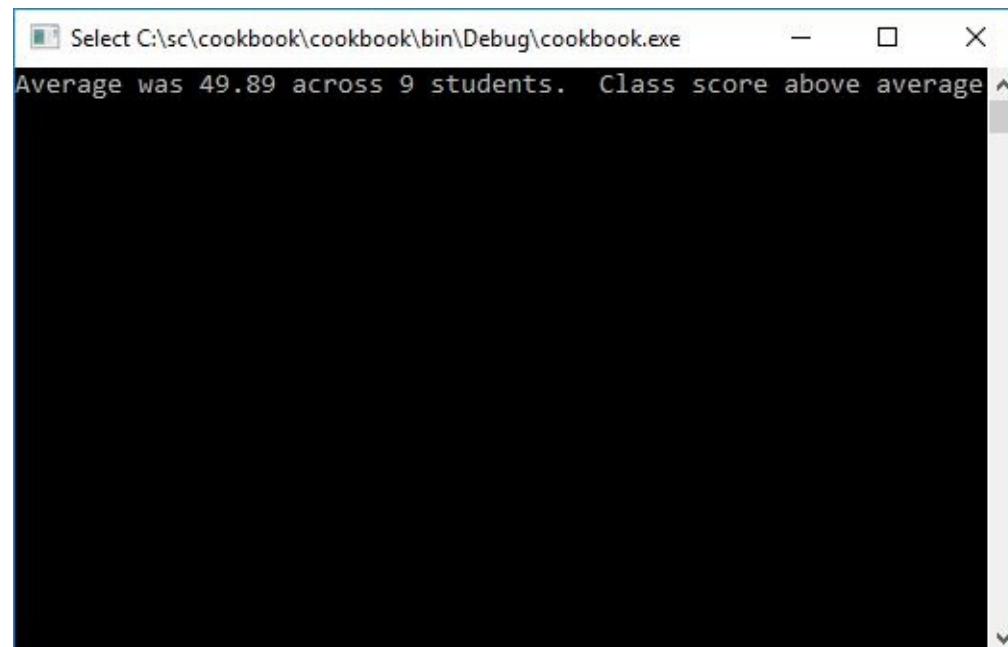

```
using static System.Math;
```

```
WriteLine($"Average was {Round(average, 2)} across {studentCount}<br/> students.
{(average < threshold ? <br/> " Class score below average." : <br/> " Class score above
average.")}");
```

```
public (double average, int studentCount, bool belowAverage) <br/>
GetAverageAndCount(int[] scores, int threshold) <br/> { <br/> var returnTuple = (ave: 0D,
sCount: 0, subAve: true); <br/> returnTuple = ((double)scores.Sum() / scores.Count(),
<br/> scores.Count(), <br/> returnTuple.ave.CheckIfBelowAverage(<br/> threshold));
<br/> return returnTuple; <br/> }

static void Main(string[] args) <br/> { <br/> int[] scores = { 17, 46, 39, 62, 81, 79, 52, 24,
49 }; <br/> Chapter1 ch1 = new Chapter1(); <br/> int threshold = 40; <br/> var (average,
studentCount, belowAverage) = <br/> ch1.GetAverageAndCount(scores, threshold); <br/>
WriteLine($"Average was {Round(average,2)} across <br/> {studentCount} students.
{(average < threshold ? <br/> " Class score below average." : <br/> " Class score above
average."})"); <br/> ReadLine(); <br/> }
```

36. Run the console application to see the correctly rounded average for the student scores.

```
returnTuple = (returnTuple.ave + 15, returnTuple.sCount - 1);
```

C# 7.0 is allowing me to first update the average value (shifting the average up) and then decrementing the count field. Tuples are a very powerful feature of C# 7.0, and it will be of great benefit to many developers when implemented it correctly.

# Pattern matching

C# 7.0 introduces an aspect common to functional programming languages with pattern matching. This new kind of construct can test values in different ways. To accomplish this, two language constructs in C# 7.0 have been enhanced to take advantage of patterns. These are as follows:

- The `is` expression
- The `case` clause in `switch` statements

With regard to the `is` expression, developers can now have a pattern on the right instead of just a type. When it comes to `switch` statements, the `case` clause can now match on patterns. The `switch` statement is no longer limited to primitive types and can switch on anything. Let's start by looking at the `is` expression.

```
using System.Collections.Generic;

public class Student<br/> {<br/>    public string Name { get; set; }<br/>    public string LastName { get; set; } <br/>    public List<int> CourseCodes { get; set; }<br/> }

public class Professor<br/> {<br/>    public string Name { get; set; }<br/>    public string LastName { get; set; }<br/>    public List<string> TeachesSubjects { get; set; }<br/> }
```

To understand where we are going with pattern matching, we first need to understand where we have come from. I will start the next section off by showing you how developers might have written this code before C# 7.0.

```

public void OutputInformation(object person)<br/> {<br/><br/> }

if (person is Student)<br/> {<br/> Student student = (Student)person;<br/>
WriteLine($"Student {student.Name} {student.LastName}<br/> is enrolled for courses
{String.Join<int>(<br/> ", ", student.CourseCodes)}");<br/> }<br/><br/> if (person is
Professor)<br/> {<br/> Professor prof = (Professor)person;<br/> WriteLine($"Professor
{prof.Name} {prof.LastName} <br/> teaches {String.Join<string>(",",
prof.TeachesSubjects)}");<br/> }

public void OutputInformation(object person)<br/> {<br/> if (person is Student)<br/>
{<br/> Student student = (Student)person;<br/> WriteLine($"Student {student.Name}
{student.LastName}<br/> is enrolled for courses {String.Join<int><br/> ("",
student.CourseCodes)}");<br/> }<br/> if (person is Professor)<br/> {<br/> Professor
prof = (Professor)person;<br/> WriteLine($"Professor {prof.Name} {prof.LastName}
<br/> teaches {String.Join<string><br/> ("", prof.TeachesSubjects)}");<br/> }<br/> }

static void Main(string[] args)<br/> {<br/> Chapter1 ch1 = new Chapter1();<br/><br/>
Student student = new Student();<br/> student.Name = "Dirk";<br/> student.LastName =
"Strauss";<br/> student.CourseCodes = new List<int> { 203, 202, 101 };<br/><br/>
ch1.OutputInformation(student);<br/><br/> Professor prof = new Professor();<br/>
prof.Name = "Reinhardt";<br/> prof.LastName = "Botha";<br/> prof.TeachesSubjects =
new List<string> {<br/> "Mobile Development", "Cryptography" };<br/><br/>
ch1.OutputInformation(prof);<br/> }

if (person is Student student)<br/> {<br/><br/> }<br/> if (person is Professor prof)<br/>
{<br/><br/> }

if (person is Student student)<br/> {<br/> WriteLine($"Student {student.Name}
{student.LastName}<br/> is enrolled for courses {String.Join<int><br/> ("",
student.CourseCodes)}");<br/> }<br/> if (person is Professor prof)<br/> {<br/>
WriteLine($"Professor {prof.Name} {prof.LastName}<br/> teaches {String.Join<string>
<br/> ("", prof.TeachesSubjects)}");<br/> }

public void OutputInformation(object person)<br/> {<br/> if (person is null)<br/>
{<br/> WriteLine($"Object {nameof(person)} is null");<br/> }<br/> }

Student student = null;

public void OutputInformation(object person)<br/> {<br/> switch (person)<br/> {<br/>
default:<br/> WriteLine("Unknown object detected");<br/> break;<br/> }<br/> }

```

```
switch (person)<br/> {<br/> case Professor prof:<br/> WriteLine($"Professor  
{prof.Name} {prof.LastName}<br/> teaches {String.Join<string><br/> (",",  
prof.TeachesSubjects)}");<br/> break;<br/> default:<br/> WriteLine("Unknown object  
detected");<br/> break;<br/> }
```

```
switch (person)<br/> {<br/> case Student student:<br/> WriteLine($"Student  
{student.Name} {student.LastName}<br/> is enrolled for courses {String.Join<int><br/>  
(", ", student.CourseCodes)}");<br/> break;<br/> case Professor prof:<br/>  
WriteLine($"Professor {prof.Name} {prof.LastName}<br/> teaches {String.Join<string>  
<br/> (",", prof.TeachesSubjects)}");<br/> break;<br/> default:<br/>  
WriteLine("Unknown object detected");<br/> break;<br/> }
```

```
switch (person)<br/> {<br/> case Student student when  
(student.CourseCodes.Contains(203)):<br/> WriteLine($"Student {student.Name}  
{student.LastName}<br/> is enrolled for course 203.");<br/> break;<br/> case Student  
student:<br/> WriteLine($"Student {student.Name} {student.LastName}<br/> is enrolled  
for courses {String.Join<int><br/> ("", student.CourseCodes)}");<br/> break;<br/> case  
Professor prof:<br/> WriteLine($"Professor {prof.Name} {prof.LastName}<br/> teaches  
{String.Join<string>(",",<br/> prof.TeachesSubjects)}");<br/> break;<br/> default:<br/>  
WriteLine("Unknown object detected");<br/> break;<br/> }
```

```
switch (person)<br/> {<br/> case Student student when  
(student.CourseCodes.Contains(203)):<br/> WriteLine($"Student {student.Name}  
{student.LastName} <br/> is enrolled for course 203.");<br/> break;<br/> case Student  
student:<br/> WriteLine($"Student {student.Name} {student.LastName} <br/> is enrolled  
for courses {String.Join<int><br/> ("", student.CourseCodes)}");<br/> break;<br/> case  
Professor prof:<br/> WriteLine($"Professor {prof.Name} {prof.LastName}<br/> teaches  
{String.Join<string><br/> ("", prof.TeachesSubjects)}");<br/> break;<br/> case null:  
<br/> WriteLine($"Object {nameof(person)} is null");<br/> break;<br/> default:<br/>  
WriteLine("Unknown object detected");<br/> break;<br/> }
```

17. Running the console application again, you will see that the first case statement containing the when condition is triggered for the Student type.

C:\sc\cookbook\cookbook\bin\Debug\cookbook.exe

- □ ×

Student Dirk Strauss is enrolled for course 203.  
Professor Reinhardt Botha teaches Mobile Development,Cryptography

# How it works...

With pattern matching, we saw that patterns are used to test whether a value is of a certain type.

*You will also hear some developers say that they test whether the value has a certain shape.*

When we find a match we can get to the information specific to that type (or shape). We saw this in the code where we accessed the `courseCodes` property, which was specific to the `Student` type and the `TeachesSubjects` property, which was specific to the `Professor` type.

Lastly, you now need to pay careful attention to the order of your `case` statements, which now matters. The `case` statement that uses the `when` clause is more specific than the statement that simply checks for a `Student` type. This means that the `when` case needs to happen before the `Student` case because both of these cases are of type `Student`. If the `student` case happens before the `when` clause, it will never trigger the `switch` for students that have course code 203.

Another important thing to remember is that the `default` clause will always be evaluated last, irrespective of where it appears in the `switch` statement. It is, therefore, good practice to write it as the last clause in a `switch` statement.

# Out variables

C# 7.0 has taken a fresh look at `out` variables. This is a small change, but really one that improves the readability and flow of the code. Previously, we first had to declare a variable to use as an `out` parameter in a method. In C# 7.0 we no longer need to do that.

# Getting ready

We will be using an often used method to test if a value is of a specific type. Yes, you guessed it, we're going to be using `TryParse`. I can already hear some of you groan (or is it just me?). Using `TryParse` is (for me anyway) such a bittersweet thing to do. It's great being able to try and parse something to test if it is valid, but the use of the `out` variable was never as neat and tidy as I would have liked. If you are not familiar with the `TryParse` method, it is a method that tests to see if a value parses to a specific type. If it does, `TryParse` will return a Boolean value of `true`; otherwise, it will return `false`.

```
string sValue = "500";<br/><br/> int intValue;<br/> if (int.TryParse(sValue, out intValue))<br/> {<br/> WriteLine($"'{intValue}' is a valid integer");<br/> // Do something with intValue<br/> }

if (int.TryParse(sValue, out intValue))<br/> {<br/> WriteLine($"'{intValue}' is a valid integer");<br/> // Do something with intValue<br/> }

if (int.TryParse(sValue, out var intValue))<br/> {<br/> WriteLine($"'{intValue}' is a valid integer");<br/> // Do something with intValue<br/> }
```

# How it works...

The changes that C# 7.0 has made to `out` variables are not major. They are, however, a major convenience to those developers who use it often. So far in this chapter, we have seen the use of Tuples, pattern matching, and `out` variables. We can easily combine some of what we have learned to create something truly unique. Consider the use of extension methods, Tuples, and `out` variables. We can easily create an extension method called `ToInt()` that has the following implementation:

```
public static (string originalValue, int integerValue, bool isInteger) ToInt(this string stringValue)
{
    var t = (original: stringValue, toIntegerValue: 0, isInt: false);
    if (int.TryParse(stringValue, out var iValue))
    {
        t.toIntegerValue = iValue; t.isInt = true;
    }
    return t;
}
```

We create a Tuple literal that will be returned in the event of the `TryParse` returning `false`. If the `TryParse` is `true`, I set the `t.toIntegerValue` and `t.isInt` values. The code that calls the extension method looks as follows:

```
var (original, intValue, isInteger) = sValue.ToInt();
if (isInteger)
{
    WriteLine($"{original} is a valid integer");
    // Do something with intValue
}
```

When you run your console application, you will see that the output is exactly the same as before. This just illustrates the power of the new features in C# 7.0 when combined with each other. Throw some pattern matching into the mix, and we will have a very potent extension method. I'll leave you folks to play around with this some more. There is a lot to discover.

# Deconstruction

Tuples can be consumed using a deconstruction declaration. This simply splits a Tuple into its individual parts and assigns these parts to new variables. This is called **deconstruction**, and it is not only reserved for Tuples.

```
var (average, studentCount) = ch1.GetAverageAndCount(scores);
```

This was deconstructing the parts of the Tuple into the new variables average and studentCount. I do not, however, want to take a look at Tuples again. What I want to do is show how you can implement a deconstruction declaration on any type. To do this, all that we need to do is ensure that the type has a deconstructor method. We will modify our existing Student class to add a deconstructor.

```
public class Student<br/> {<br/> public string Name { get; set; }<br/> public string  
LastName { get; set; }<br/> public List<int> CourseCodes { get; set; }<br/> }  
  
public void Deconstruct(out string name, out string lastName)<br/> {<br/> name = Name;  
<br/> lastName = LastName;<br/> }
```

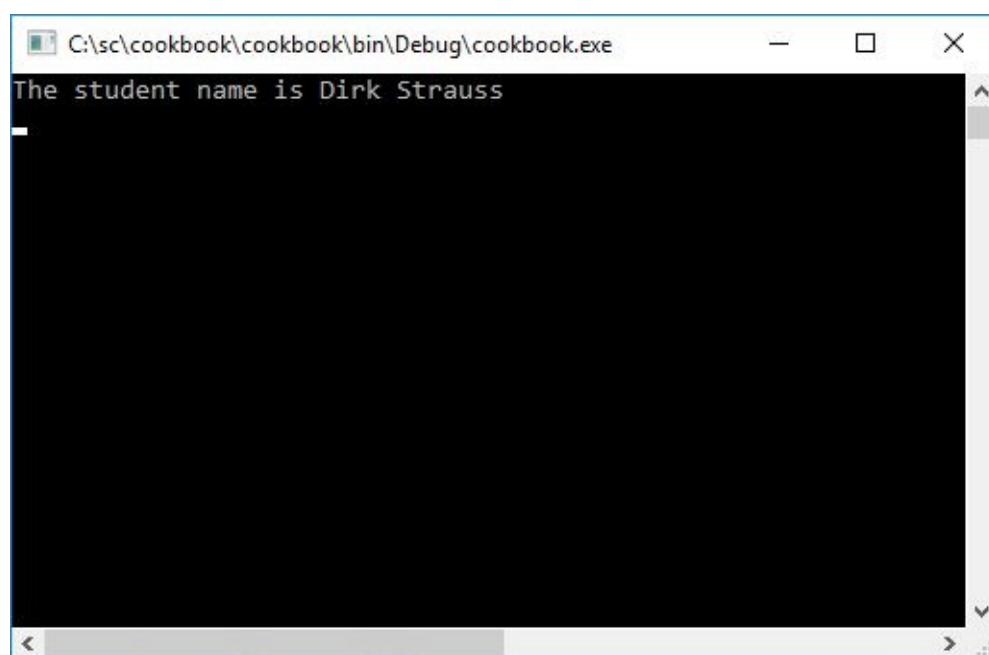

```
public class Student<br/> {<br/> public string Name { get; set; }<br/> public string  
LastName { get; set; }<br/> public List<int> CourseCodes { get; set; }<br/><br/> public  
void Deconstruct(out string name, out string lastName)<br/> {<br/> name = Name;<br/>  
lastName = LastName;<br/> }<br/> }
```

```
Student student = new Student();<br/> student.Name = "Dirk";<br/> student.LastName =  
"Strauss";<br/><br/> var (FirstName, Surname) = student;<br/> WriteLine($"The student  
name is {FirstName} {Surname}");
```

```
public class Student<br/> {<br/> public string Name { get; set; }<br/> public string  
LastName { get; set; }<br/> public List<int> CourseCodes { get; set; }<br/> }
```

```
public static void Deconstruct(this Student student, <br/> out string firstItem, out string  
secondItem)<br/> {<br/> firstItem = student.Name;<br/> secondItem =  
student.LastName;<br/> }
```

8. The extension method acts on a `Student` type only. It follows the same basic implementation of the deconstructor created earlier in the `Student` class itself. Running the console application again, you will see the same result as before. The only difference is that the code is now using the extension method to deconstruct values in the `Student` class.

```
Student student = new Student(studentNumber);
```

```
public class Student<br/>{<br/>    public Student(string studentNumber)<br/>    {<br/>        (Name, LastName) = GetStudentDetails(studentNumber);<br/>    }<br/>    public string Name<br/>    { get; private set; }<br/>    public string LastName { get; private set; }<br/>    public List<int> CourseCodes { get; private set; }<br/><br/>    public void Deconstruct(out string name, out string lastName)<br/>    {<br/>        name = Name;<br/>        lastName = LastName;<br/>    }<br/><br/>    private (string name, string surname) GetStudentDetails(string studentNumber)<br/>    {<br/>        var detail = (n: "Dirk", s: "Strauss");<br/>        // Do something with student number to return the student details<br/>        return detail;<br/>    }<br/>}
```

```
Student student = new Student("S20323742");<br/>var (FirstName, Surname) = student;<br/>WriteLine($"The student name is {FirstName} {Surname}");
```

# Local functions

The use of local functions might seem a little strange at first. They are in fact quite often used in most functional languages. C# 7.0 now allows us to do the same. So what exactly is a local function? Well, think of it as a helper method for a specific method. This helper method only really makes sense when used from the specific method and will not be useful for other methods in your application. It, therefore, makes sense to use it *inside* your existing method. Some might think that an extension method might be just as well suited, but extension methods should really be used to extend the functionality of many other methods. The usefulness of local functions will become evident in the following code example.

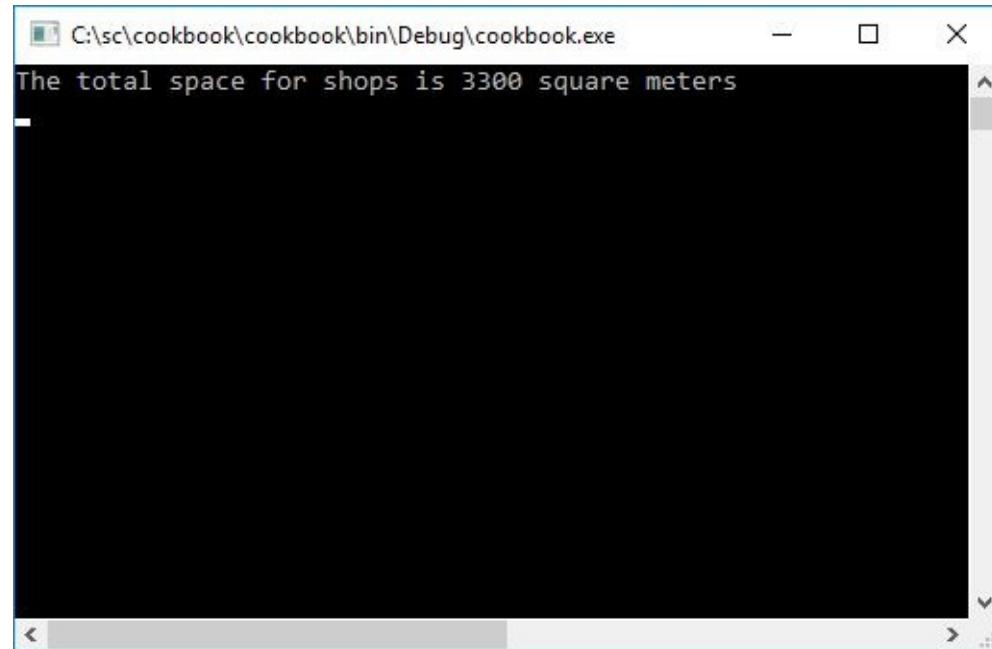

# Getting ready

There is nothing you need to specifically get ready or set up beforehand to be able to use local functions. To illustrate the use of local functions, I will create a method that calculates the floor space of a building after the common area space has been subtracted from the total floor space.

```
public Building GetShopfloorSpace(int floorCommonArea,<br/> int buildingWidth, int  
buildingLength)<br/> {<br/><br/> }  
  
public class Building<br/> { <br/> public int TotalShopFloorSpace { get; set; } <br/> }  
  
int CalculateShopFloorSpace(int common, int width, int length)<br/> {<br/> return  
(width * length) - common;<br/> }  
  
public Building GetShopfloorSpace(int floorCommonArea,<br/> int buildingWidth, int  
buildingLength)<br/> {<br/> Building building = new Building();<br/><br/>  
building.TotalShopFloorSpace = CalculateShopFloorSpace(<br/> floorCommonArea,  
buildingWidth, buildingLength);<br/><br/> int CalculateShopFloorSpace(int common, int  
width, int length)<br/> {<br/> return (width * length) - common;<br/> }<br/><br/>  
return building;<br/> }  
  
Chapter1 ch1 = new Chapter1();<br/> Building bldng = ch1.GetShopfloorSpace(200, 35,  
100);<br/> WriteLine($"The total space for shops is <br/> {bldng.TotalShopFloorSpace}  
square meters");
```

6. Run your console application and see the output displayed as follows:

# How it works...

The beauty of local functions is that you can call them from anywhere inside your method. To illustrate this, add the following line of code just before the `return` statement of the `GetShopfloorSpace()` method. This essentially overrides whatever we passed to the method initially.

```
| building.TotalShopFloorSpace = CalculateShopFloorSpace(10, 9, 17);
```

The modified method will now look like this:

```
public Building GetShopfloorSpace(int floorCommonArea, int buildingWidth, int buildingLength)
{
    Building building = new Building();

    building.TotalShopFloorSpace = CalculateShopFloorSpace(
        floorCommonArea, buildingWidth, buildingLength);

    int CalculateShopFloorSpace(int common, int width, int length)
    {
        return (width * length) - common;
    }

    building.TotalShopFloorSpace = CalculateShopFloorSpace(10, 9, 17);

    return building;
}
```

Run your console application again. This time you will see that the values are totally different. The second call to the local function overrode the first call and illustrates that the local function can be called throughout the method containing it.

I can think of a few instances where I might have been able to use this in the past. It isn't something I think that I'll use often. It is however a very nice addition to the C# language and great that it is available to developers.

# Improvements to literals

This is another minor improvement to the C# language, but one that I'm sure will often be used by developers. One of my first jobs as a young man was working for a logistics company. These folks used to supply parts to Volkswagen, and the most critical parts were flown in by air freight from Germany or elsewhere. I will never forget the 9- and 12-digit shipping numbers the logistics people used to throw around in casual conversation. I wondered how they were able to remember literally hundreds of varying shipping numbers during the course of a year. After listening to them for a while, I noticed that they were saying these numbers with slight pauses after every third number. Even just looking at the 12-digit number 395024102833 is visually taxing. Imagine doing this several times a day, including memorizing the fast movers on the next shipment (I'm not even going to go into the printed shipment manifest, which was a nightmare). It is, therefore, easier to think of the number as 395-024-102-833 and this makes it easier to spot patterns. This is essentially exactly what C# 7.0 now allows developers to do with literals.

# Getting ready

Number literals can sometimes be difficult to read. This is why C# 7.0 introduces the underscore (\_) to act as a digit separator inside of number literals. C# 7.0 also introduces binary literals, which allow you to specify bit patterns directly without needing to know hexadecimal.

```
var oldNum = 342057239127493;<br/> var newNum = 342_057_239_127_493;<br/>  
WriteLine($"oldNum = {oldNum} and newNum = {newNum}");
```

```
var binLit = 0b1010_1100_0011_0010_0001_0000;
```

# **How it works...**

This is merely syntactical sugar for literals. I'm sure that there is much more to it going on in the background, but the implementation of this in your code is really straightforward.

# Ref returns and locals

Passing objects by reference in C# is nothing new. This is done using the `ref` keyword. In C# 7.0, however, you can now return objects by reference and store these objects in a local variable by reference.

# Getting ready

It is important to understand the concept of the `ref` keyword. When you pass a `ref` parameter, you are working with the variable itself, not just the value of the variable. This means that, if the value is changed, the original place in memory is updated, not only the value which would be a copy of the parameter. This becomes clearer in the following example.

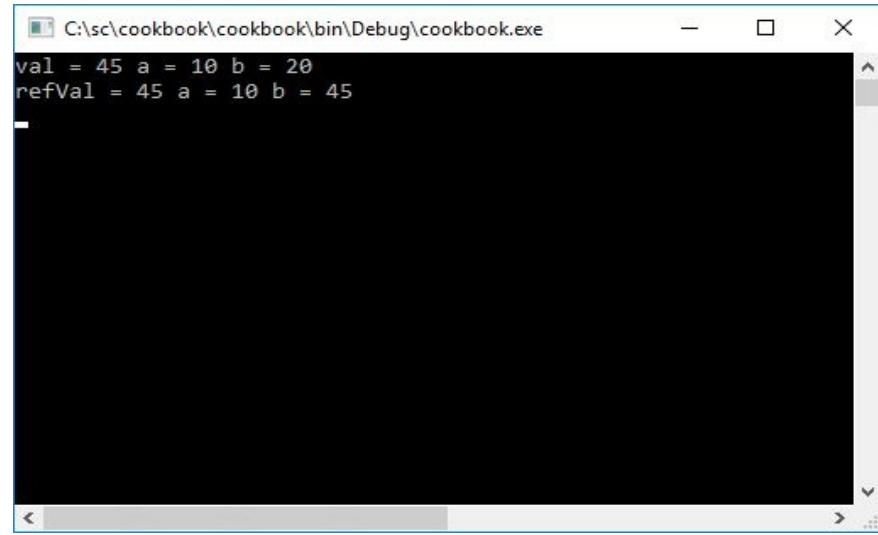

```
public int GetLargest(int valueA, int valueB){  
    if (valueA > valueB)  
        return valueA;  
    else  
        return valueB;  
}
```

```
public ref int GetLargest(ref int valueA, ref int valueB){  
    if (valueA > valueB)  
        return ref valueA;  
    else  
        return ref valueB;  
}
```

```
int a = 10;  
int b = 20;  
Chapter1 ch1 = new Chapter1();  
int val =  
ch1.GetLargest(a, b);  
val += 25;  
WriteLine($"val = {val} a = {a} b = {b}");
```

```
ref int refVal = ref ch1.GetLargest(ref a, ref b);  
refVal += 25;  
WriteLine($"refVal = {refVal} a = {a} b = {b}");
```

5. Run your console application and consider the output displayed.

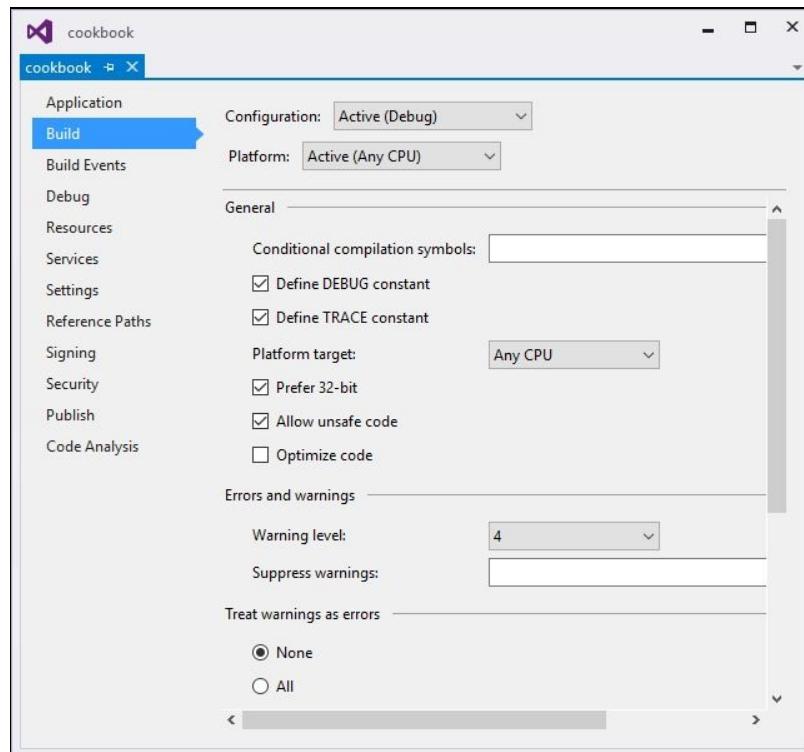

# How it works...

In the console window, you will see two very different results. Simply put, in the first line, the variable `a` is the variable `a`, the variable `b` is the variable `b`, and the variable `val` is the variable `val`.

In the second line, the variable `a` is the variable `a`, the variable `b` is the variable `b`, and the variable `refVal` is the variable `b`. This is the whole crux of the `ref` keyword. In the first `GetLargest()` method, we returned the largest value into the variable `val`. This value was 20. The variable `val` and the variable `b` had no relation to one another as they were allocated different spaces in memory.

In the second `GetLargest()` method, we returned the largest variable itself (which was `b`) into the variable `refVal`. The variable `refVal` therefore becomes an alias of the variable `b` because they both point to the same space allocated in memory. To illustrate this even more clearly, let us have a look at the memory addresses for the variables.

From the Project menu, go to the Properties of the current project. In the Build tab, check the option to Allow unsafe code and save the properties.

Add the following code to your console application: unsafe

```
{  
IntPtr a_var_memoryAddress = (IntPtr)(&a);  
IntPtr b_var_memoryAddress = (IntPtr)(&b);  
IntPtr val_var_memoryAddress = (IntPtr)(&val);
```

```
fixed (int* refVal_var = &refVal)  
{  
IntPtr refVal_var_memoryAddress = (IntPtr)(refVal_var);
```

```
WriteLine($"The memory address of a is {a_var_memoryAddress}");  
WriteLine($"The memory address of b is {b_var_memoryAddress}");  
WriteLine($"The memory address of val is {val_var_memoryAddress}");  
WriteLine($"The memory address of refVal is  
{refVal_var_memoryAddress}");  
}  
}
```

*This code is not really related to the recipe on `ref` returns and locals, so I'm not even going to go into it in any detail. If you want to learn more about pointers in C#, start with the MSDN article on Pointer types (C# Programming Guide): <https://msdn.microsoft.com/en-us/library/y31yhkeb.aspx>.*

Run your console application and take a look at the memory addresses listed:

The screenshot shows a Windows Command Prompt window titled "C:\sc\cookbook\cookbook\bin\Debug\cookbook.exe". The window contains the following text:  
The memory address of a is 11531256  
The memory address of b is 11531252  
The memory address of val is 11531244  
The memory address of refVal is 11531252

You will notice straightaway that variable `b` and variable `refVal` have the same memory address of `11531252`, while variable `b` and variable `val` have different memory addresses.

So now for the million dollar question: Why is this feature in C# 7.0 even useful? Well, simply put, it can improve performance. Many developers mention that it will be quite useful for game programmers, who can now pass these aliases around to reference large data structures. This means that they don't have to make a copy of a large array (for example) in order to work with it. Using `ref`, they can create an alias that points to the original memory location of the array and read or modify it directly. Thinking of it this way suddenly brings the usefulness of this C# 7.0 feature into perspective.

Will I ever use it? I don't really know. Perhaps not often but, as with local functions, this feature of C# 7.0 is really a great addition to the developer's toolkit. It solves some really tricky problems when you want to get away from copying around large structures in your code.

# Generalized async return types

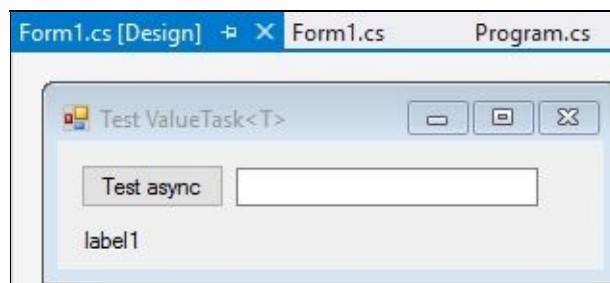

If you use `async/await` (if not, check it out) the following feature of C# 7.0 will come in really handy. The only supported return types used to be `Task<T>`, `Task`, and `void`. Even then, `void` was also only used with event handlers such as a button click. The challenge, however, was that a `Task<T>` was allocated in situations where the result of the `async` operation was available at the time of awaiting. But, what does this even mean? Well consider an `async` method that returns a `Task<T> :` and that value has a time to live of  $n$  amount of seconds. If the `async` method is called within the time to live period, why go to the trouble of allocating another `Task<T>` object? This is where the `ValueTask<T>` comes into play; it will allow other types to be defined so that you can return them from an `async` method. This, therefore, reduces the `Task<T>` allocations, which in turn will lead to performance gains.

# Getting ready

Start off by creating a new WinForms application and performing the following steps:

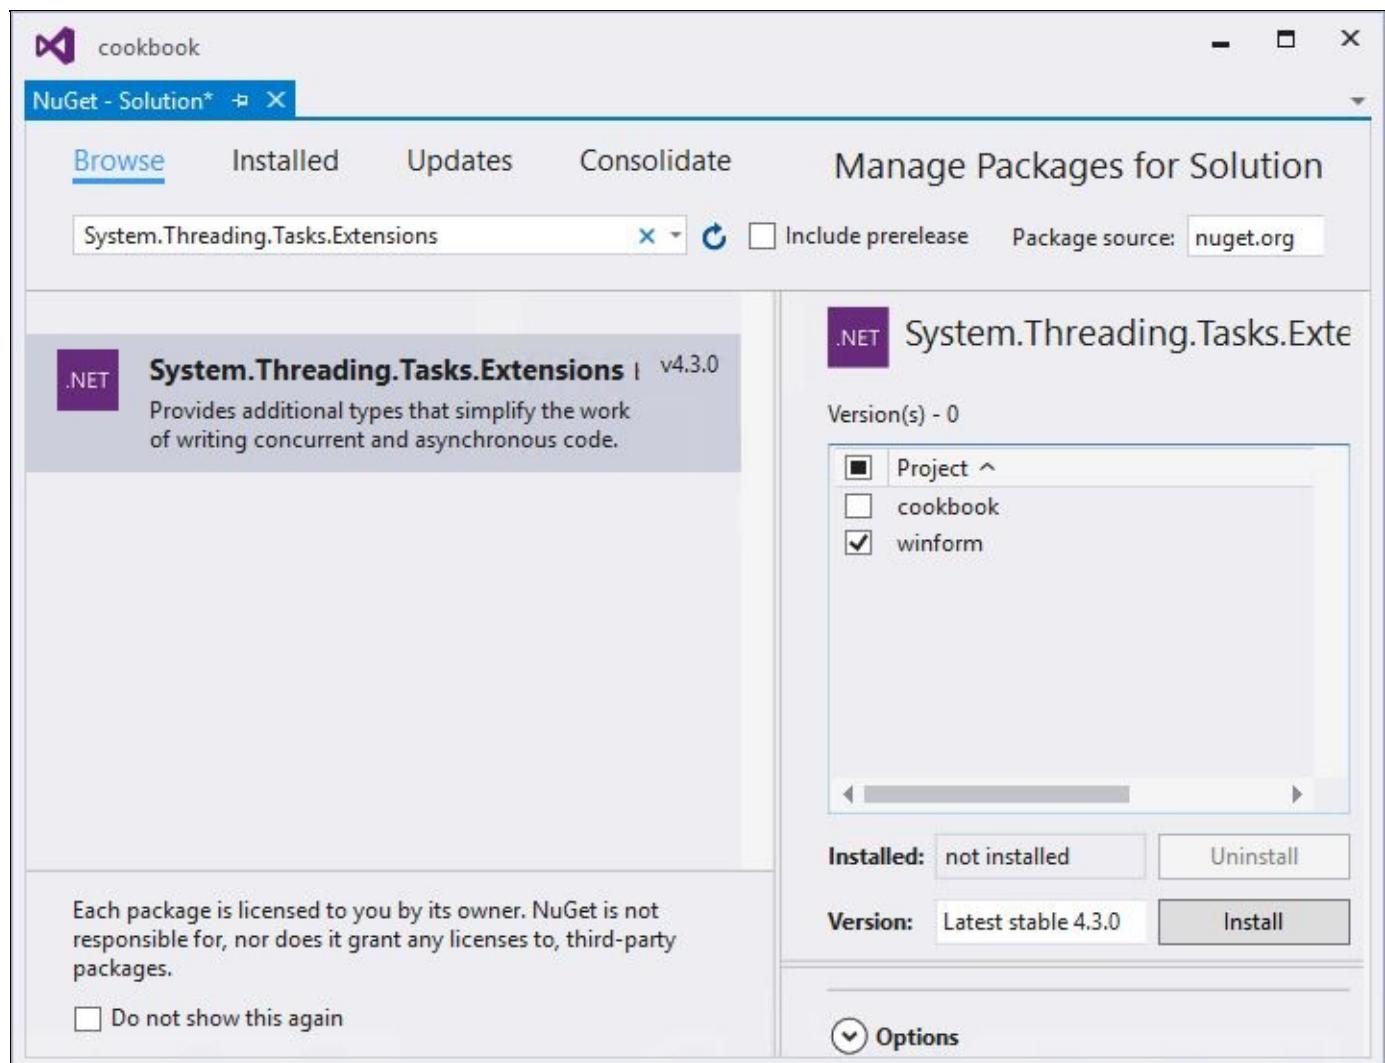

1. Add a button, label, timer, and textbox to the Windows form.

2. We need to add the `System.Threading.Tasks.Extensions` package from NuGet to implement the `ValueTask<T>` struct. This process should be familiar to you if you completed the Tuples recipe. Select the winform project and click on the Install button.

*Note that I am using Visual Studio 2017 RC while writing this book. You probably will not need to add `System.Threading.Tasks.Extensions` from NuGet in the final release.*

3. A confirmation screen will be displayed to allow you to review the changes that are about to be made. Just click on OK. Accept the license agreement. Also make sure that you have added this `using` statement to your project.

```
| using System.Threading.Tasks;
```

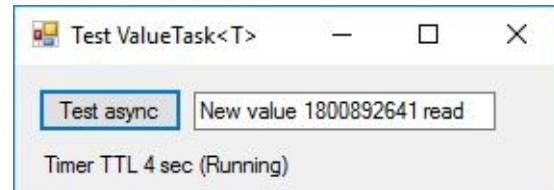

We are now ready to write our code. The Windows app will call an `async Task<T>` method if the time to live has passed. Once it does that, the method will read a value and cache it. This cached value will be valid for 10 seconds (which is the time to live). If the method is run within the time to live period, then the cached value will be used and returned to the form. If the time to live has passed, the process repeats and the `Task<T>` method is called. The implementation will become clearer when you review the following code samples.

```
double timerTtl = 10.0D;  
private DateTime timeToLive;  
private int cacheValue;  
  
private void Form1_Load(object sender, EventArgs e)  
{  
    lblTimer.Text =  
        $"Timer TTL {timerTtl} sec (Stopped)";  
}  
  
private void timer1_Tick(object sender, EventArgs e)  
{  
    if (timerTtl == 0)  
    {  
        timerTtl = 5;  
    }  
    else  
    {  
        timerTtl -= 1;  
    }  
    lblTimer.Text =  
        $"Timer TTL {timerTtl} sec (Running)";  
}  
  
public async Task<int> GetValue()  
{  
    await Task.Delay(1000);  
    Random r = new Random();  
    cacheValue = r.Next();  
    timeToLive =  
        DateTime.Now.AddSeconds(timerTtl);  
    timer1.Start();  
    return cacheValue;  
}
```

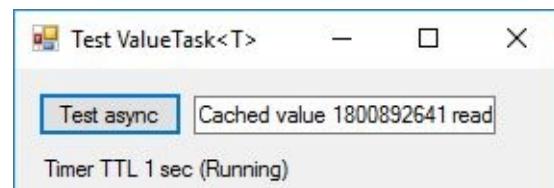

```
public ValueTask<int> LoadReadCache(out bool blnCached)  
{  
    if (timeToLive < DateTime.Now)  
    {  
        blnCached = false;  
        return new ValueTask<int>(GetValue());  
    }  
    else  
    {  
        blnCached = true;  
        return new ValueTask<int>(cacheValue);  
    }  
}
```

```
private async void btnTestAsync_Click(object sender, EventArgs e)  
{  
    int iVal =  
        await LoadReadCache(out bool isCachedValue);  
    if (isCachedValue)  
    {  
        txtOutput.Text =  
            $"Cached value {iVal} read";  
    }  
    else  
    {  
        txtOutput.Text =  
            $"New value {iVal} read";  
    }  
}
```

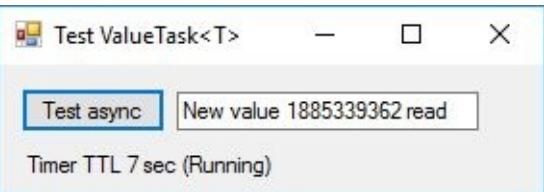

- When you finish adding all the code, run your application and click on the Test async button. This will read a new value from the `GetValue()` method, cache it, and start the time to live count down.

- If you click on the button again before the time to live has expired, the cached value is returned.

9. When the time to live expires, clicking on the Test async button will call the GetValue( ) method again and the process repeats.

# How it works...

`valueTask<T>` is a very nice addition to C# 7.0. Microsoft, however, does suggest that you benchmark the performance of `Task<T>` versus `valueTask<T>` when doing additional optimizing of your methods. A simple optimization however would be to simply replace the instances of `Task<T>` with `valueTask<T>`.

# Expression bodies for accessors, constructors, and finalizers

Expression-bodied members have been a big hit with the C# developer community, so much so that Microsoft has expanded the allowed members that can be implemented as expressions. You can now use this feature with:

- Constructors
- Finalizers (used when you need to release unmanaged code)
- `get` and `set` accessors on properties and indexers

# Getting ready

There is nothing you specifically need to get ready in order to use this recipe. The following code will make use of an old-versus-new approach to demonstrate the differences and implementation of each.

```
public class SomeClass<br/> {<br/> private int _initialValue;<br/><br/> // Property<br/>  
public int initialValue<br/> {<br/> get<br/> {<br/> return _initialValue;<br/> }<br/><br/>  
set<br/> {_initialValue = value;<br/> }<br/> }<br/><br/> // Constructor<br/>  
public SomeClass(int initialValue)<br/> {<br/> initialValue = initialValue;<br/> }<br/>  
<br/> // Finalizer<br/> ~SomeClass()<br/> {<br/> WriteLine("Release unmanaged code");  
<br/> }<br/> }
```

```
public class SomeClass<br/> {<br/> private int _initialValue;<br/><br/> public int  
InitialValue<br/> {<br/> get => _initialValue;<br/> set => _initialValue = value;<br/> }  
<br/><br/> public SomeClass(int initialValue) => <br/> initialValue = initialValue;<br/>  
<br/> ~SomeClass() => WriteLine("Release unmanaged code");<br/> }
```

# How it works...

If you have used expression-bodied members before in C# 6.0, you will undoubtedly be excited to use the expanded functionality. Personally, I'm really glad that constructors can now be implemented as an expression.

# **throw expressions**

Traditionally, `throw` has been a statement in C#. As we know, because it is a statement and not an expression, we could not use it in certain places. Thanks to expression-bodied members, C# 7.0 introduced `throw` expressions. There isn't any difference in how an exception is thrown, only in where you can throw them from.

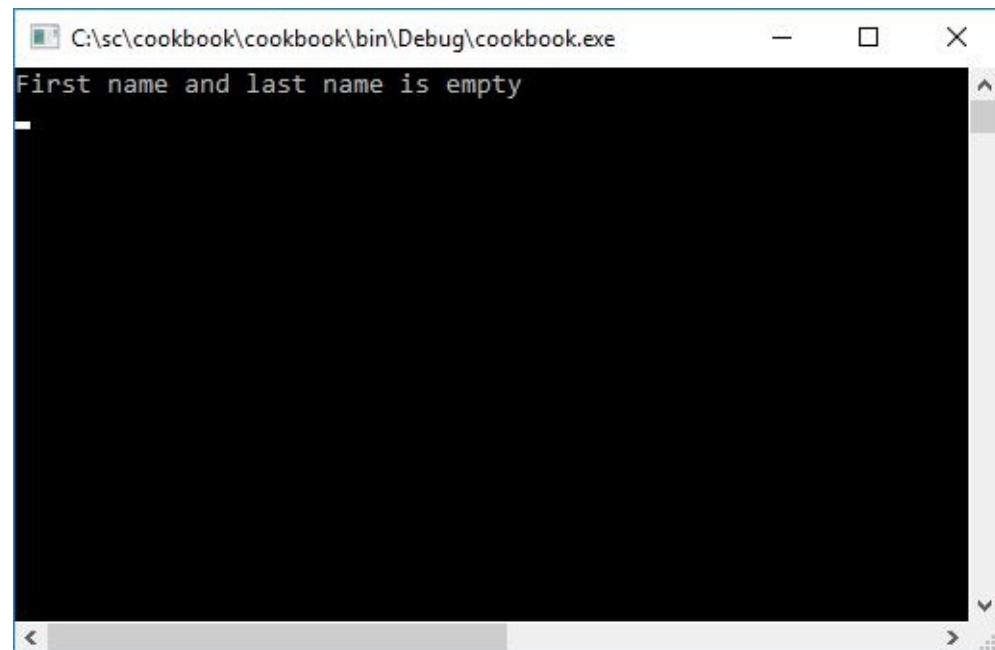

# Getting ready

Throwing exceptions is nothing new. You have been doing it ever since you have been writing code. I will admit that `throw` expressions are a very welcome addition to C# and it's all thanks to expression-bodied members.

```
public int GetNameLength(string firstName, string lastName)<br/> {<br/> return  
(firstName.Length + lastName.Length) > 0 ? <br/> firstName.Length + lastName.Length :  
throw new <br/> Exception("First name and last name is empty");<br/> }
```

```
try<br/> {<br/> Chapter1 ch1 = new Chapter1();<br/> int nameLength =  
ch1.GetNameLength("", "");<br/> }<br/> catch (Exception ex)<br/> {<br/>  
WriteLine(ex.Message);<br/> }
```

3. Running your console application will then return the exception message as the output.

# How it works...

Being able to use `throw` expressions makes your code easier to write and easier to read. The new features in C# 7.0 build on top of the fantastic foundation laid down by C# 6.0.

# Classes and Generics

Classes form the building blocks of software development and are essential for building good code. In this chapter, we will be looking at classes and generics and why we need to use them. The recipes we will be covering are as follows:

- Creating and implementing an abstract class
- Creating and implementing an interface
- Creating and using a generic class or method
- Creating and using a generic interface

# Introduction

As you probably know, classes are simply containers for related methods and properties to describe an object in your software. An object is an instance of a specific class and, sometimes, mimics real-world things. When thinking of a car, you might create a vehicle class that contains certain attributes (properties) that all vehicles contain, such as automatic or manual transmission, wheel count (not all vehicles have only four wheels), or fuel type.

When we create an instance of the vehicle class, we can create a car object, an SUV object, and so on. Here lies the power of classes, which is to describe the world around us and translate it into a programming language that a compiler can understand.

# Creating and implementing an abstract class

Many developers have heard about abstract classes, but their implementation is a mystery. How can you as a developer identify an abstract class and decide when to use one? The definition is quite a simple one actually. Once you understand this fundamental definition of an abstract class, when and why to use one becomes obvious.

Imagine for a moment that you are developing an application that manages the animals in a cat sanctuary. The cat sanctuary rehabilitates lions, tigers, jaguars, leopards, cheetahs, pumas, and even domestic cats. The common noun that describes all these animals is the word *cat*. You can, therefore, safely assume that the abstraction of all these animals is a cat, and thus, this word identifies our abstract class. You would then create an abstract class called `cat`.

However, you need to keep in mind that you will never ever create an instance of the abstract class `cat`. All the classes that inherit from the abstract class also share some functionality. This means that you will create a `Lion` class and a `Tiger` class that inherit from the abstract class `cat`. In other words, the inherited classes are a kind of `cat`. Both classes share functionality in the form of `sleep()`, `Eat()`, `Hunt()`, and various other methods. In this way, we can ensure that inherited classes all contain this common functionality.

# Getting ready

Let's go ahead and create our abstract class for cat. We will then use it to inherit from and create other objects to define different types of cats.

```
public abstract class Cat<br/> {<br/><br/> }

class Program<br/> {<br/> static void Main(string[] args)<br/> {<br/> }<br/> }<br/>
<br/> public abstract class Cat<br/> {<br/><br/> }

public abstract class Cat <br/> { <br/> public abstract void Eat();<br/> public abstract
void Hunt();<br/> public abstract void Sleep();<br/> }

public class Lion <br/> { <br/><br/> }

public class Lion : Cat <br/> { <br/><br/> }

public class Lion : Cat <br/> { <br/> public override void Eat() <br/> { <br/> throw new
NotImplementedException();<br/> } <br/><br/> public override void Hunt() <br/> {
<br/> throw new NotImplementedException();<br/> } <br/><br/> public override void
Sleep() <br/> { <br/> throw new NotImplementedException();<br/> } <br/> }

using static System.Console;

public override void Eat() <br/> { <br/> WriteLine($"The {LionColor} lion eats.");<br/>
} <br/><br/> public override void Hunt() <br/> { <br/> WriteLine($"The {LionColor}
lion hunts.");<br/> } <br/><br/> public override void Sleep() <br/> { <br/>
WriteLine($"The {LionColor} lion sleeps.");<br/> }

public class Tiger : Cat <br/> { <br/> public override void Eat() <br/> { <br/> throw new
NotImplementedException();<br/> } <br/><br/> public override void Hunt() <br/> {
<br/> throw new NotImplementedException();<br/> } <br/><br/> public override void
Sleep() <br/> { <br/> throw new NotImplementedException();<br/> } <br/> }

public override void Eat() <br/> { <br/> WriteLine($"The {TigerColor} tiger eats.");<br/>
} <br/><br/> public override void Hunt() <br/> { <br/> WriteLine($"The
{TigerColor} tiger hunts.");<br/> } <br/><br/> public override void Sleep() <br/> {
<br/> WriteLine($"The {TigerColor} tiger sleeps.");<br/> }

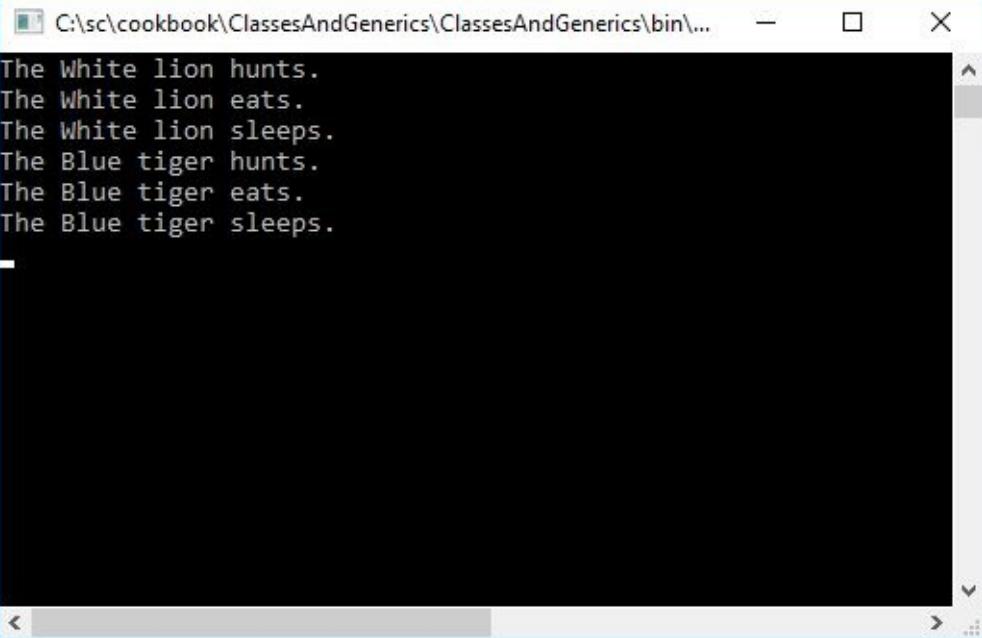

public enum ColorSpectrum { Brown, White } <br/> public string LionColor { get; set; }

public Lion(ColorSpectrum color) <br/> { <br/> LionColor = color.ToString();<br/> }

public enum ColorSpectrum { Orange, White, Gold, Blue, Black } <br/> public string
TigerColor { get; set; }
```

```
public Tiger(ColorSpectrum color) {  
    TigerColor = color.ToString();  
}  
  
Lion lion = new Lion(Lion.ColorSpectrum.White);  
lion.Hunt();  
lion.Eat();  
lion.Sleep();  
  
Tiger tiger = new Tiger(Tiger.ColorSpectrum.Blue);  
tiger.Hunt();  
tiger.Eat();  
tiger.Sleep();  
  
ReadLine();
```

19. When you run your console application, you see that the methods are called in sequence:

```
The White lion hunts.  
The White lion eats.  
The White lion sleeps.  
The Blue tiger hunts.  
The Blue tiger eats.  
The Blue tiger sleeps.
```

# How it works...

While the example illustrated earlier is a rather simplistic one, the theory is sound. The abstract class takes collective functionality across all cats and groups so that it can be shared inside each derived class. No implementation exists in the abstract class; it only defines what needs to happen. Think of abstract classes as a type of blueprint for classes that inherit from the abstract class.

While the content of the implementation is up to you, the abstract class requires that you add the abstract methods it defines. From here on, you can create a solid foundation for similar classes in your applications that are supposed to share functionality. This is the goal of inheritance. Let's recap the features of an abstract class:

- You can't instantiate an abstract class with the `new` keyword.
- You can only add abstract methods and accessors to an abstract class.
- You can never modify an abstract class as `sealed`. The `sealed` modifier prevents inheritance, while `abstract` requires inheritance.
- Any class derived from your abstract class must include the implementations of the abstract methods that were inherited from the abstract class.
- Because abstract methods inside the abstract class have no implementation, they don't contain a body either.

# Creating and implementing an interface

For many developers, interfaces are equally confusing and their purpose not clearly understood. Interfaces are actually quite easy to get to grips with once you understand the concept that defines an interface.

Interfaces act like verbs. So, for example, if we had to create two classes called `Lion` and `Tiger` that derive from the `cat` abstract class, the interface would describe some sort of action. Lions and tigers can roar (but not purr). We can then create an interface called `IRoarable`. If we had to derive a class called `Cheetah` from our abstract class `cat`, we would not be able to use the `IRoarable` interface, because cheetahs purr. We would need to create an `IPurrable` interface.

# Getting ready

Creating an interface is very similar to creating an abstract class. The difference is that the interface is describing what the class can do, in the case of the `Cheetah` class, by implementing `IPurrable`.

```
public abstract class Cat <br/> { <br/> public abstract void Eat(); <br/> public abstract void Hunt(); <br/> public abstract void Sleep(); <br/> }

public class Cheetah : Cat <br/> { <br/><br/> }

public class Cheetah : Cat <br/> { <br/> public override void Eat() <br/> { <br/> throw new NotImplementedException(); <br/> } <br/><br/> public override void Hunt() <br/> { <br/> throw new NotImplementedException(); <br/> } <br/><br/> public override void Sleep() <br/> { <br/> throw new NotImplementedException(); <br/> } <br/> }

public class Cheetah : Cat <br/> { <br/> public override void Eat() <br/> { <br/> WriteLine($"The cheetah eats."); <br/> } <br/><br/> public override void Hunt() <br/> { <br/> WriteLine($"The cheetah hunts."); <br/> } <br/><br/> public override void Sleep() <br/> { <br/> WriteLine($"The cheetah sleeps."); <br/> } <br/> }

interface IPurrable <br/> { <br/><br/> }

interface IPurrable <br/> { <br/> void SoftPurr(int decibel); <br/> }

public class Cheetah : Cat, IPurrable <br/> { <br/> public override void Eat() <br/> { <br/> WriteLine($"The cheetah eats."); <br/> } <br/><br/> public override void Hunt() <br/> { <br/> WriteLine($"The cheetah hunts."); <br/> } <br/><br/> public override void Sleep() <br/> { <br/> WriteLine($"The cheetah sleeps."); <br/> } <br/> }

public class Cheetah : Cat, IPurrable <br/> { <br/> public void SoftPurr(int decibel) <br/> { <br/> throw new NotImplementedException(); <br/> } <br/><br/> public override void Eat() <br/> { <br/> WriteLine($"The cheetah eats."); <br/> } <br/><br/> public override void Hunt() <br/> { <br/> WriteLine($"The cheetah hunts."); <br/> } <br/><br/> public override void Sleep() <br/> { <br/> WriteLine($"The cheetah sleeps."); <br/> } <br/> }

public class Cheetah : Cat, IPurrable <br/> { <br/> public int SoftPurr { get; set; } <br/> <br/> public void SoftPurr(int decibel) <br/> { <br/> throw new NotImplementedException(); <br/> } <br/><br/> public override void Eat() <br/> { <br/> WriteLine($"The cheetah eats."); <br/> } <br/><br/> public override void Hunt() <br/> { <br/> WriteLine($"The cheetah hunts."); <br/> } <br/><br/> public override void Sleep() <br/> { <br/> WriteLine($"The cheetah sleeps."); <br/> } <br/> }

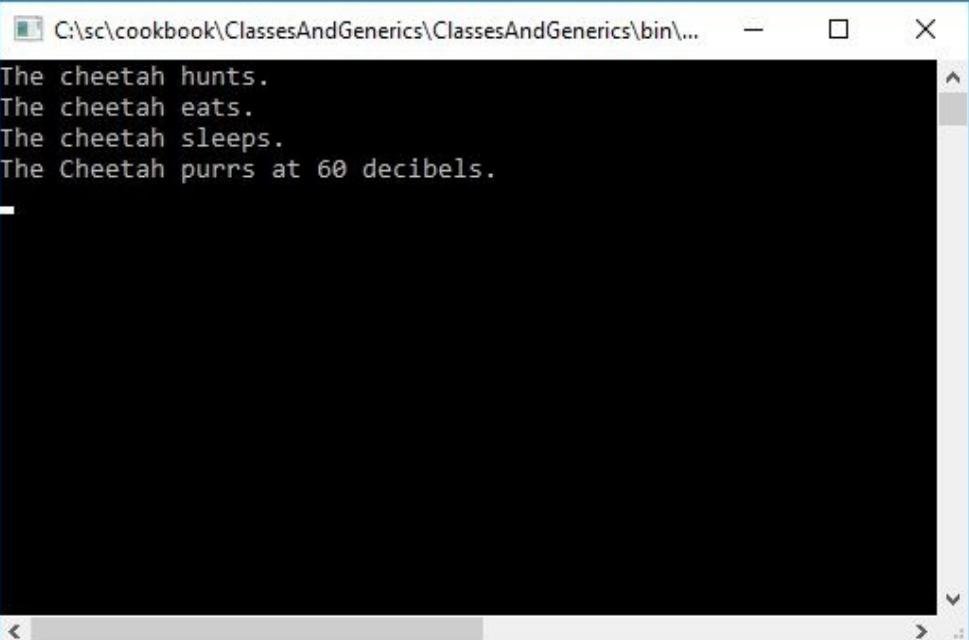

public class Cheetah : Cat, IPurrable <br/> { <br/> public int SoftPurr { get; set; } <br/> <br/> void IPurrable.SoftPurr(int decibel) <br/> { <br/> throw new
```

```
NotImplementedException();<br/> } <br/><br/> public override void Eat() <br/> { <br/>  
WriteLine($"The cheetah eats."); <br/> } <br/><br/> public override void Hunt() <br/> {  
<br/> WriteLine($"The cheetah hunts."); <br/> } <br/><br/> public override void Sleep()  
<br/> { <br/> WriteLine($"The cheetah sleeps."); <br/> } <br/> }
```

```
public void SoftPurr(int decibel) <br/> { <br/> WriteLine($"The {nameof(Cheetah)}  
purrs at {decibel} decibels."); <br/> }
```

```
Cheetah cheetah = new Cheetah(); <br/> cheetah.Hunt(); <br/> cheetah.Eat(); <br/>  
cheetah.Sleep(); <br/> cheetah.SoftPurr(60); <br/> ReadLine();
```

19. Running the application will produce the following output:

```
The cheetah hunts.  
The cheetah eats.  
The cheetah sleeps.  
The Cheetah purrs at 60 decibels.
```

# How it works...

So, you might be wondering what the difference between an abstract class and an interface is. It basically comes down to where you want your implementation. If you need to share functionality between derived classes, then an abstract class is the best fit for your needs. In other words, we had specific things that were common to all cats (lions, tigers, and cheetahs) such as hunting, eating, and sleeping. This is then best used within an abstract class.

If your implementation is specific to a class or several classes (but not all classes), then your best course of action would be to use an interface. In this case, the `IPurrable` interface can be applied to several classes (for example, cheetahs and domestic cats) but can't be applied to all cats (such as lions and tigers), because not all cats can purr.

Knowing this difference and where you need to place your implementation will aid you in deciding whether you need to use an abstract class or an interface.

# **Creating and using a generic class or method**

Generics is a very interesting way of writing code. Instead of specifying the data type of the elements in the code at design time, you can actually delay the specification of those elements until they are used in code. This basically means that your class or method can work with any data type.

# Getting ready

We will start off by writing a generic class that can take any data type as a parameter in its constructor and do something with it.

# How to do it...

1. Declaring a generic class is actually very easy. All that we need to do is create the class with the generic type parameter <T>:

```
public class PerformAction<T>
{
}
```

*The generic type parameter is basically a placeholder for a specific type that will need to be defined when the class or variable is instantiated. This means that the generic class `PerformAction<T>` can never just be used without specifying the type argument inside angle brackets when instantiating the class.*

2. Next, create a `private` variable of the generic type parameter `T`. This will hold the value we pass to the generic class:

```
public class PerformAction<T>
{
    private T _value;
}
```

3. We now need to add a constructor to the generic class. The constructor will take as parameter a value of type `T`. The private variable `_value` will be set to the parameter passed to the constructor:

```
public class PerformAction<T>
{
    private T _value;

    public PerformAction(T value)
    {
        _value = value;
    }
}
```

4. Finally, to complete our generic class, create a void return method called `IdentifyDataType()`. All that this is going to do is tell us what data type we passed to the generic class. We can find the type of the variable using `GetType()`:

```
public class PerformAction<T>
{
    private T _value;

    public PerformAction(T value)
    {
        _value = value;
    }

    public void IdentifyDataType()
    {
        WriteLine($"The data type of the supplied variable
                  is {_value.GetType()}");
    }
}
```

5. To see the true beauty of our generic class in action, instantiate the generic class in the console application and specify different data type arguments inside the angle brackets of each new instantiation:

```

PerformAction<int> iAction = new PerformAction<int>(21);
iAction.IdentifyDataType();

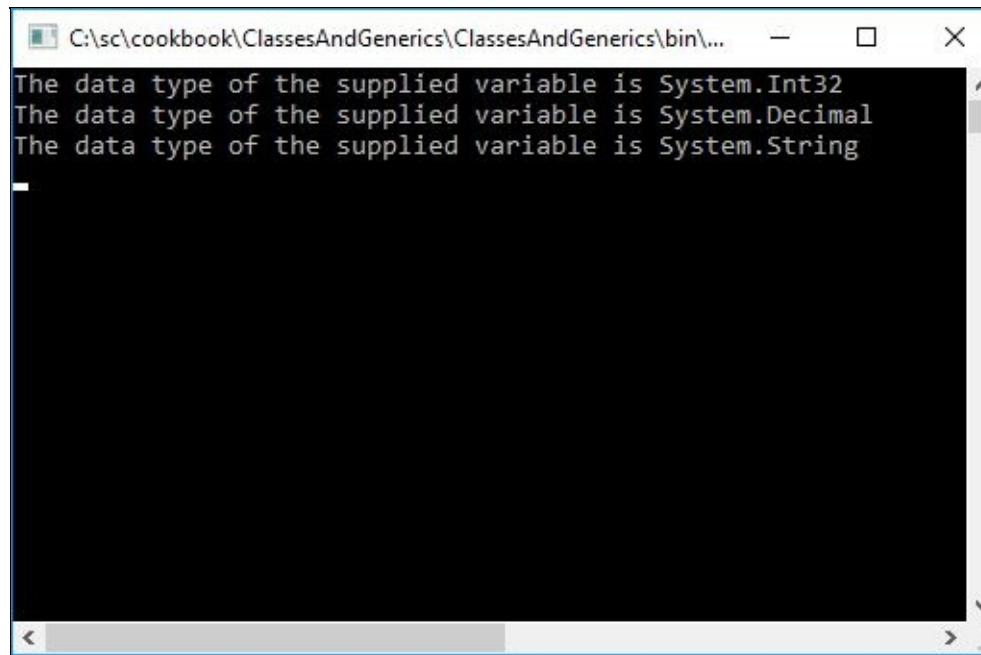

PerformAction<decimal> dAction = new
                                PerformAction<decimal>(21.55m);
dAction.IdentifyDataType();

PerformAction<string> sAction = new
                                PerformAction<string>("Hello Generics");
sAction.IdentifyDataType();

ReadLine();

```

6. Running your console application will output the given data types that you instantiated the generic class with each time:

We used the exact same class but let it perform with three very different data types. This kind of flexibility is a very powerful feature in your code.

Another feature of C# is that you can constrain the generic types implemented:

1. We can do this by telling the compiler that only types that implement the `IDisposable` interface can be used with the generic class. Change your generic class by adding `where T : IDisposable` to it. Your generic class should now look like this:

```

public class PerformAction<T> where T : IDisposable
{
    private T _value;

    public PerformAction(T value)
    {
        _value = value;
    }

    public void IdentifyDataType()
    {
        WriteLine($"The data type of the supplied variable
                  is {_value.GetType()}");
    }
}

```

2. Go back to the console application and take a look at the previous instantiations of the generic class:

```

PerformAction<int> iAction = new PerformAction<int>(21);
iAction.IdentifyDataType();

PerformAction<decimal> dAction = new PerformAction<decimal>(21.55m);
dAction.IdentifyDataType();

PerformAction<string> sAction = new PerformAction<string>("Hello Generics");
sAction.IdentifyDataType();

```

Visual Studio will tell you that the types underlined by the red squiggly lines do not implement `IDisposable` and therefore can't be supplied to the `PerformAction` generic class.

3. Comment out those lines of code and add the following instantiation to your console application:

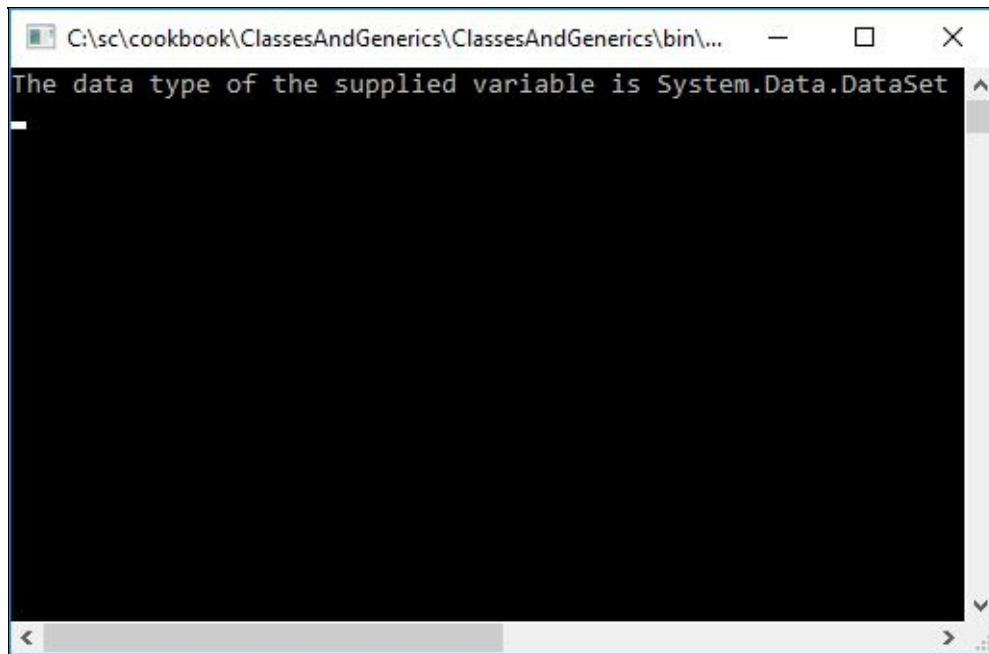

```

DataSet dsData = new DataSet();
PerformAction<DataSet> oAction = new
    PerformAction<DataSet>(dsData);
oAction.IdentifyDataType();

```

 Note that for this to work, you might need to add `using System.Data;` to your code file. This is needed so that you can declare a `dataset`.

4. As you might know, a `dataset` type implements `IDisposable` and therefore it is a valid type to pass to our generic class. Go ahead and run the console application:

The `Dataset` type is valid, and the generic class performs as expected, identifying the type of the parameter passed to the constructor.

But what about generic methods? Well, just like generic classes, generic methods also do not specify their type at design time. It is only known when the method is called. Let's take a look at the following implementation of the generic methods:

1. Let's go ahead and create a new helper class called `MyHelperClass`:

```
public class MyHelperClass
{
}
```

- Inside this helper class, we will create a generic method called `InspectType`. What is interesting about this generic method is that it can return multiple types because the return type is also marked with the generic type parameter. Your generic method does not have to return anything. It can also be declared as `void`:

```
public class MyHelperClass
{
    public T InspectType<T>(T value)
    {
        }
}
```

- To illustrate that this generic method can return multiple types, we will output the type passed to the generic method to the console window and then return that type and display it in the console application. You will notice that you need to cast the return type as `(T)` when returning it:

```
public class MyHelperClass
{
    public T InspectType<T>(T value)
    {
        WriteLine($"The data type of the supplied parameter
is {value.GetType()}");

        return (T)value;
    }
}
```

- In the console application, go ahead and create an enumerator called `MyEnum`. The generic method can also accept enumerators:

```
public enum MyEnum { Value1, Value2, Value3 }
```

- After creating the enumerator, add the following code to the console application. We are instantiating and calling the `oHelper` class and passing different values to it:

```
MyHelperClass oHelper = new MyHelperClass();
var intExample = oHelper.InspectType(25);
WriteLine($"An example of this type is {intExample}");

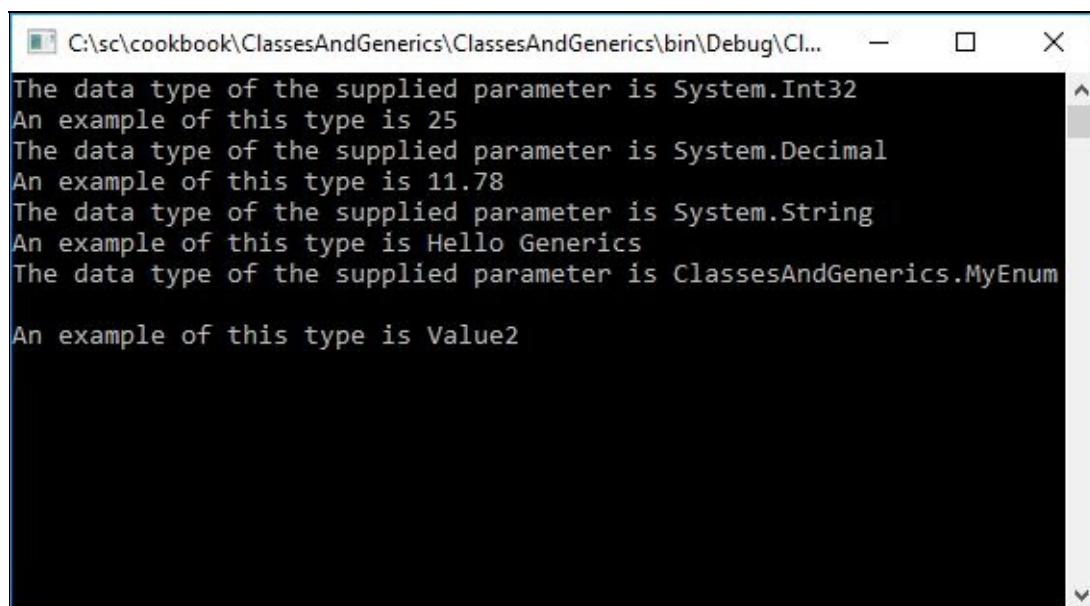

var decExample = oHelper.InspectType(11.78m);
WriteLine($"An example of this type is {decExample}");

var strExample = oHelper.InspectType("Hello Generics");
WriteLine($"An example of this type is {strExample}");

var enumExample = oHelper.InspectType(MyEnum.Value2);
WriteLine($"An example of this type is {enumExample}");

ReadLine();
```

- If you run the console application, you will see that the generic method correctly identifies the type of the parameter passed to it and then returns that type to the calling code in the console application:

The data type of the supplied parameter is System.Int32  
An example of this type is 25  
The data type of the supplied parameter is System.Decimal  
An example of this type is 11.78  
The data type of the supplied parameter is System.String  
An example of this type is Hello Generics  
The data type of the supplied parameter is ClassesAndGenerics.MyEnum  
  
An example of this type is Value2

Generic methods can be used in a multitude of situations. This is, however, only an introduction to generic classes and methods. It is recommended that you do further research to learn how to implement generics in your code appropriately.

# How it works...

At the heart of generics lies the ability to reuse a single class or method. It allows developers to essentially not repeat similar code throughout your code base. This conforms well to the **Don't Repeat Yourself (DRY)** principle. This design principle states that a specific bit of logic should be represented in code only once.

Using generic classes, for example, also allows developers to create a class that is type safe when compiling. Type safe basically means that the developer can be assured of the type of the object and can use the class in a specific way without experiencing any unexpected behavior. Therefore, the compiler takes over the burden of type safety.

Generics also allow developers to write less code, because code can be reused and less code also performs better.

# Creating and using a generic interface

Generic interfaces work in much the same way as the previous examples in generics. Let's assume that we want to find the properties of certain classes in our code, but we can't be sure how many classes we will need to inspect. A generic interface could come in very handy here.

# Getting ready

We need to inspect several classes for their properties. To do this, we will create a generic interface that will return a list of all the properties found for a class as a list of strings.

```

interface IListClassProperties<T> <br/> { <br/> List<string> GetPropertyList(); <br/> }

public class InspectClass<T> : IListClassProperties<T> <br/> { <br/><br/> }

public class InspectClass<T> : IListClassProperties<T> <br/> { <br/> public List<string> GetPropertyList() <br/> { <br/> throw new NotImplementedException(); <br/> } <br/> }

public class InspectClass<T> : IListClassProperties<T> <br/> { <br/> T _classToInspect;
<br/> public InspectClass(T classToInspect) <br/> { <br/> _classToInspect =
classToInspect; <br/> } <br/><br/> public List<string> GetPropertyList() <br/> { <br/>
throw new NotImplementedException(); <br/> } <br/> }

public List<string> GetPropertyList() <br/> { <br/> return _classToInspect.GetType()
<br/> .GetProperties().Select(p => p.Name).ToList(); <br/> }

public class Invoice <br/> { <br/> public int ID { get; set; } <br/> public decimal
TotalValue { get; set; } <br/> public int LineNumber { get; set; } <br/> public string
StockItem { get; set; } <br/> public decimal ItemPrice { get; set; } <br/> public int Qty {
get; set; } <br/> }

Invoice oInvoice = new Invoice(); <br/> InspectClass<Invoice> oClassInspector = new
<br/> InspectClass<Invoice>(oInvoice); <br/> List<string> lstProps =
oClassInspector.GetPropertyList(); <br/><br/> foreach(string property in lstProps) <br/>
{ <br/> WriteLine(property); <br/> } <br/> ReadLine();

InspectClass<int> oClassInspector = new InspectClass<int>(10); <br/> List<string>
lstProps = oClassInspector.GetPropertyList(); <br/> foreach (string property in lstProps)
<br/> { <br/> WriteLine(property); <br/> } <br/> ReadLine();

public class InspectClass<T> : IListClassProperties<T><br/> where T : class <br/> {
<br/> T _classToInspect; <br/> public InspectClass(T classToInspect) <br/> { <br/>
_classToInspect = classToInspect; <br/> } <br/><br/> public List<string>
GetPropertyList() <br/> { <br/> return _classToInspect.GetType().GetProperties()<br/>
.Select(p => p.Name).ToList(); <br/> } <br/> }

public abstract class AcmeObject <br/> { <br/> public abstract int ID { get; set; } <br/> }

public class InspectClass<T> : IListClassProperties<T><br/> where T : AcmeObject
<br/> { <br/> T _classToInspect; <br/> public InspectClass(T classToInspect) <br/> {
<br/> _classToInspect = classToInspect; <br/> } <br/><br/> public List<string>
GetPropertyList() <br/> { <br/> return _classToInspect.GetType().GetProperties()<br/>
```

```
.Select(p => p.Name).ToList(); <br/> } <br/> }
```

```
public class Invoice : AcmeObject <br/> { <br/> public override int ID { get; set; } <br/> public decimal TotalValue { get; set; } <br/> public int LineNumber { get; set; } <br/> public string StockItem { get; set; } <br/> public decimal ItemPrice { get; set; } <br/> public int Qty { get; set; } <br/> }
```

```
public class SalesOrder : AcmeObject <br/> { <br/> public override int ID { get; set; } <br/> public decimal TotalValue { get; set; } <br/> public int LineNumber { get; set; } <br/> public string StockItem { get; set; } <br/> public decimal ItemPrice { get; set; } <br/> public int Qty { get; set; } <br/> } <br/><br/> public class CreditNote <br/> { <br/> public int ID { get; set; } <br/> public decimal TotalValue { get; set; } <br/> public int LineNumber { get; set; } <br/> public string StockItem { get; set; } <br/> public decimal ItemPrice { get; set; } <br/> public int Qty { get; set; } <br/> }
```

```
Invoice oInvoice = new Invoice(); <br/> InspectClass<Invoice> oInvClassInspector = new <br/> InspectClass<Invoice>(oInvoice); <br/> List<string> invProps = oInvClassInspector.GetPropertyList(); <br/><br/> foreach (string property in invProps) <br/> { <br/> WriteLine(property); <br/> } <br/> ReadLine(); <br/> SalesOrder oSalesOrder = new SalesOrder(); <br/> InspectClass<SalesOrder> oSoClassInspector = new <br/> InspectClass<SalesOrder>(oSalesOrder); <br/> List<string> soProps = oSoClassInspector.GetPropertyList(); <br/><br/> foreach (string property in soProps) <br/> { <br/> WriteLine(property); <br/> } <br/> ReadLine();
```

6. If, however, we had to try do the same for our `CreditNote` class, we will see that Visual Studio will warn us that we can't pass the `CreditNote` class to the `InspectClass<T>` class because the constraint we implemented only accepts objects that derive from our `AcmeObject` abstract class. By doing this, we have effectively taken control over exactly what we allow to be passed to our generic class and interface by means of constraints:

```
CreditNote oCreditNote = new CreditNote();
InspectClass<CreditNote> oCredClassInspector = new InspectClass<CreditNote>(oCreditNote);
List<string> credProps = oCredClassInspector.GetPropertyList();

foreach (string property in credProps)
{
    WriteLine(property);
}
ReadLine();
```

# How it works...

Speaking of generic interfaces, we have seen that we can implement behavior on a generic class by implementing a generic interface. The power of using the generic class and generic interface is well illustrated earlier.

Having said that, we do believe that knowing when to use constraints is also important so that you can close down your generic classes to only accept specific types that you want. This ensures that you don't get any surprises when someone accidentally passes an integer to your generic class.

Finally, the constraints that you can use are as follows:

- where `T: struct`: The type argument must be any value types
- where `T: class`: The type argument must be any reference types
- where `T: new()`: The type argument needs to have a parameterless constructor
- where `T: <base class name>`: The type argument must derive from the given base class
- where `T: <T must derive from object>`: `T` The type arg was must derive must derive from the object after the colon
- where `T: <interface>`: The type argument must implement the interface specified

# Object-Oriented Programming in C#

This chapter will introduce you to the foundation of C# and **object-oriented programming (OOP)**. In this chapter, you will cover the following recipes:

- Using inheritance in C#
- Using abstraction
- Leveraging encapsulation
- Implementing polymorphism
- Single responsibility principle
- Open/closed principle
- Exception handling

# Introduction

During your career as a creator of software, you will hear the term OOP many times. This design philosophy allows for objects to exist independently and can be reused by different sections of code. This is all made possible by what we refer to as the four pillars of OOP: inheritance, encapsulation, abstraction, and polymorphism.

In order to grasp this, you need to start thinking of objects (which are basically instantiated classes) that perform a specific task. Classes need to adhere to the SOLID design principle. This principle is explained here:

- Single responsibility principle (SRP)
- Open/closed principle
- Liskov substitution principle (LSP)
- Interface segregation principle
- Dependency inversion principle

Let's start off with an explanation of the four pillars of OOP, after which we will take a look at the SOLID principle in more detail.

# Using inheritance in C#

In today's world, inheritance is usually associated with the end of things. In OOP, however, it is associated with the beginning of something new and better. When we create a new class, we can take an already existing class and inherit it on our new class. This means that our new object will have all the features of the inherited class as well as the additional features added to the new class. This is at the root of inheritance. We call a class that inherits from another a derived class.

# Getting ready

To illustrate the concept of inheritance, we will create a few classes that inherit from another to form new, more feature-rich objects.

```
public class SpaceShip <br/> { <br/><br/> }

public class SpaceShip <br/> { <br/> public void ControlBridge() <br/> { <br/><br/> }
<br/> public void MedicalBay(int patientCapacity) <br/> { <br/><br/> } <br/> public
void EngineRoom(int warpDrives) <br/> { <br/><br/> } <br/> public void
CrewQuarters(int crewCapacity) <br/> { <br/><br/> } <br/> public void
TeleportationRoom() <br/> { <br/><br/> } <br/> }

public class Destroyer : SpaceShip <br/> { <br/><br/> }

public class Destroyer : SpaceShip <br/> { <br/> public void WarRoom() <br/> { <br/>
<br/> } <br/> public void Armory(int payloadCapacity) <br/> { <br/><br/> } <br/><br/>
public void WarSpecialists(int activeBattalions) <br/> { <br/><br/> } <br/> }

public class Annihilator : Destroyer <br/> { <br/><br/> }

public class Annihilator : Destroyer <br/> { <br/> public void TractorBeam() <br/> {
<br/><br/> } <br/><br/> public void PlanetDestructionCapability() <br/> { <br/><br/> }
<br/> }

SpaceShip transporter = new SpaceShip(); <br/> transporter.ControlBridge(); <br/>
transporter.CrewQuarters(1500); <br/> transporter.EngineRoom(2); <br/>
transporter.MedicalBay(350); <br/> transporter.TeleportationRoom();

Destroyer warShip = new Destroyer(); <br/> warShip.Armory(6); <br/>
warShip.ControlBridge(); <br/> warShip.CrewQuarters(2200); <br/>
warShip.EngineRoom(4); <br/> warShip.MedicalBay(800); <br/>
warShip.TeleportationRoom(); <br/> warShip.WarRoom(); <br/>
warShip.WarSpecialists(1);

Annihilator planetClassDestroyer = new Annihilator(); <br/>
planetClassDestroyer.Armory(12); <br/> planetClassDestroyer.ControlBridge(); <br/>
planetClassDestroyer.CrewQuarters(4500); <br/> planetClassDestroyer.EngineRoom(7);
<br/> planetClassDestroyer.MedicalBay(3500); <br/>
planetClassDestroyer.PlanetDestructionCapability(); <br/>
planetClassDestroyer.TeleportationRoom(); <br/> planetClassDestroyer.TractorBeam();
<br/> planetClassDestroyer.WarRoom(); <br/> planetClassDestroyer.WarSpecialists(3);
```

# How it works...

We can see that inheritance allows us to easily extend our classes by reusing functionality that already exists within another class created earlier. You also need to be aware though that any changes to the `Spaceship` class will be inherited, all the way up to the top-most derived class.

Inheritance is a very powerful feature of C# that allows developers to write less code, and reuse working and tested methods.

# Using abstraction

With abstraction, we take from the object we want to create the basic functionality that all objects derived from the abstracted object must have. To explain this in simple terms, we abstract the common functionality and put it in a single class that will be used to provide this shared functionality to all classes that inherit from it.

# Getting ready

To explain abstraction, we will use abstract classes. Imagine that you are dealing with trainee space astronauts who need to progress through the ranks as they get trained. The truth is that once you as trainee learn a new skill, that skill is learned and will remain with you even though you learn more advanced ways to do things. You must also implement all the previous skills learned in the new object you create. Abstract classes demonstrate this concept very nicely.

```
public abstract class SpaceCadet <br/> { <br/> public abstract void ChartingStarMaps();  
<br/> public abstract void BasicCommunicationSkill(); <br/> public abstract void  
BasicWeaponsTraining(); <br/> public abstract void Negotiation(); <br/> }  
  
public abstract class SpacePrivate : SpaceCadet <br/> { <br/> public abstract void  
AdvancedCommunicationSkill(); <br/> public abstract void  
AdvancedWeaponsTraining(); <br/> public abstract void Persuader(); <br/> }  
  
public class LabResearcher : SpaceCadet <br/> { <br/><br/> }  
  
public class LabResearcher : SpaceCadet <br/> { <br/> public override void  
BasicCommunicationSkill() <br/> { <br/> throw new NotImplementedException(); <br/> }  
<br/><br/> public override void BasicWeaponsTraining() <br/> { <br/>  
throw new NotImplementedException(); <br/> } <br/><br/> public override void  
ChartingStarMaps() <br/> { <br/> throw new NotImplementedException(); <br/> } <br/>  
<br/> public override void Negotiation() <br/> { <br/>  
throw new NotImplementedException(); <br/> } <br/> }  
  
public class PlanetExplorer : SpacePrivate <br/> { <br/><br/> }  
  
public class PlanetExplorer : SpacePrivate <br/> { <br/> public override void  
AdvancedCommunicationSkill() <br/> { <br/> throw new NotImplementedException();  
<br/> } <br/><br/> public override void AdvancedWeaponsTraining() <br/> { <br/>  
throw new NotImplementedException(); <br/> } <br/><br/> public override void  
BasicCommunicationSkill() <br/> { <br/> throw new NotImplementedException(); <br/> }  
<br/><br/> public override void BasicWeaponsTraining() <br/> { <br/> throw new  
NotImplementedException(); <br/> } <br/><br/> public override void  
ChartingStarMaps() <br/> { <br/> throw new NotImplementedException(); <br/> } <br/>  
<br/> public override void Negotiation() <br/> { <br/> throw new  
NotImplementedException(); <br/> } <br/><br/> public override void Persuader() <br/>  
<br/> { <br/> throw new NotImplementedException(); <br/> } <br/> }
```

# How it works...

Abstraction has allowed us to define a common set of functionality that is to be shared among all the classes that derive from the abstract classes. The difference between inheriting from the abstract class and a normal class is that with an abstract class, you have to implement all the methods defined in that abstract class.

This makes the class easy to version and change. If you need to add new functionality, you can do so by adding that functionality to the abstract class without breaking any of the existing code. Visual Studio will require that all inherited classes implement the new method defined in the abstract class.

You can, therefore, be assured that the change applied will be implemented in all your classes that derive from the abstract classes in your code.

# Leveraging encapsulation

What is encapsulation? Simply put, it is hiding the inner workings of a class that aren't necessary for the implementation of that class. Think of encapsulation as follows: most people who own a car know that it runs on gas- they don't need to know the inner working of an internal combustion engine to be able to use a car. They only need to know that they need to fill it up with gas when it is close to empty and that they need to check the oil and tyre pressure. Even then, it is usually not done by the car owner. This is true for classes and encapsulation.

The owner of the class is the one who uses it. The inner workings of that class need not be exposed to the developer using the class. The class is, therefore, like a black box. You know that the class will be consistent in its functionality, given the correct set of parameters. How exactly the class gets to the output is of no concern to the developer as long as the input is correct.

# Getting ready

To illustrate the concept of encapsulation, we will create a class that is somewhat complex in its inner working. We need to calculate the **thrust-to-weight ratio (TWR)** of a space shuttle to determine whether it will be able to take off vertically. It needs to exert more thrust than its weight to counteract gravity and get into a stable orbit. This also depends on which planet the shuttle takes off, because different planets exert different gravitational forces on objects on their surface. In simple terms, the TWR must be greater than one.

```
public class LaunchShuttle {  
    private double _EngineThrust;  
    private double _TotalShuttleMass;  
    private double _LocalGravitationalAcceleration;  
  
    private const double EarthGravity = 9.81;  
    private const double MoonGravity = 1.63;  
    private const double MarsGravity = 3.75;  
    private double UniversalGravitationalConstant;  
  
    public enum Planet { Earth, Moon, Mars }  
}
```

```
public LaunchShuttle(double engineThrust, double totalShuttleMass, double gravitationalAcceleration) {  
    _EngineThrust = engineThrust;  
    _TotalShuttleMass = totalShuttleMass;  
    _LocalGravitationalAcceleration = gravitationalAcceleration;  
}  
  
public LaunchShuttle(double engineThrust, double totalShuttleMass, Planet planet) {  
    _EngineThrust = engineThrust;  
    _TotalShuttleMass = totalShuttleMass;  
    SetGravitaionalAcceleration(planet);  
}  
  
public LaunchShuttle(double engineThrust, double totalShuttleMass, double planetMass, double planetRadius) {  
    _EngineThrust = engineThrust;  
    _TotalShuttleMass = totalShuttleMass;  
    SetUniversalGravitationalConstant();  
    _LocalGravitationalAcceleration = Math.Round(CalculateGravitationalAcceleration(planetRadius, planetMass), 2);  
}
```

```
private void SetGravitaionalAcceleration(Planet planet) {  
    switch (planet)  
    {  
        case Planet.Earth:  
            _LocalGravitationalAcceleration = EarthGravity;  
            break;  
        case Planet.Moon:  
            _LocalGravitationalAcceleration = MoonGravity;  
            break;  
        case Planet.Mars:  
            _LocalGravitationalAcceleration = MarsGravity;  
            break;  
        default:  
            break;  
    }  
}
```

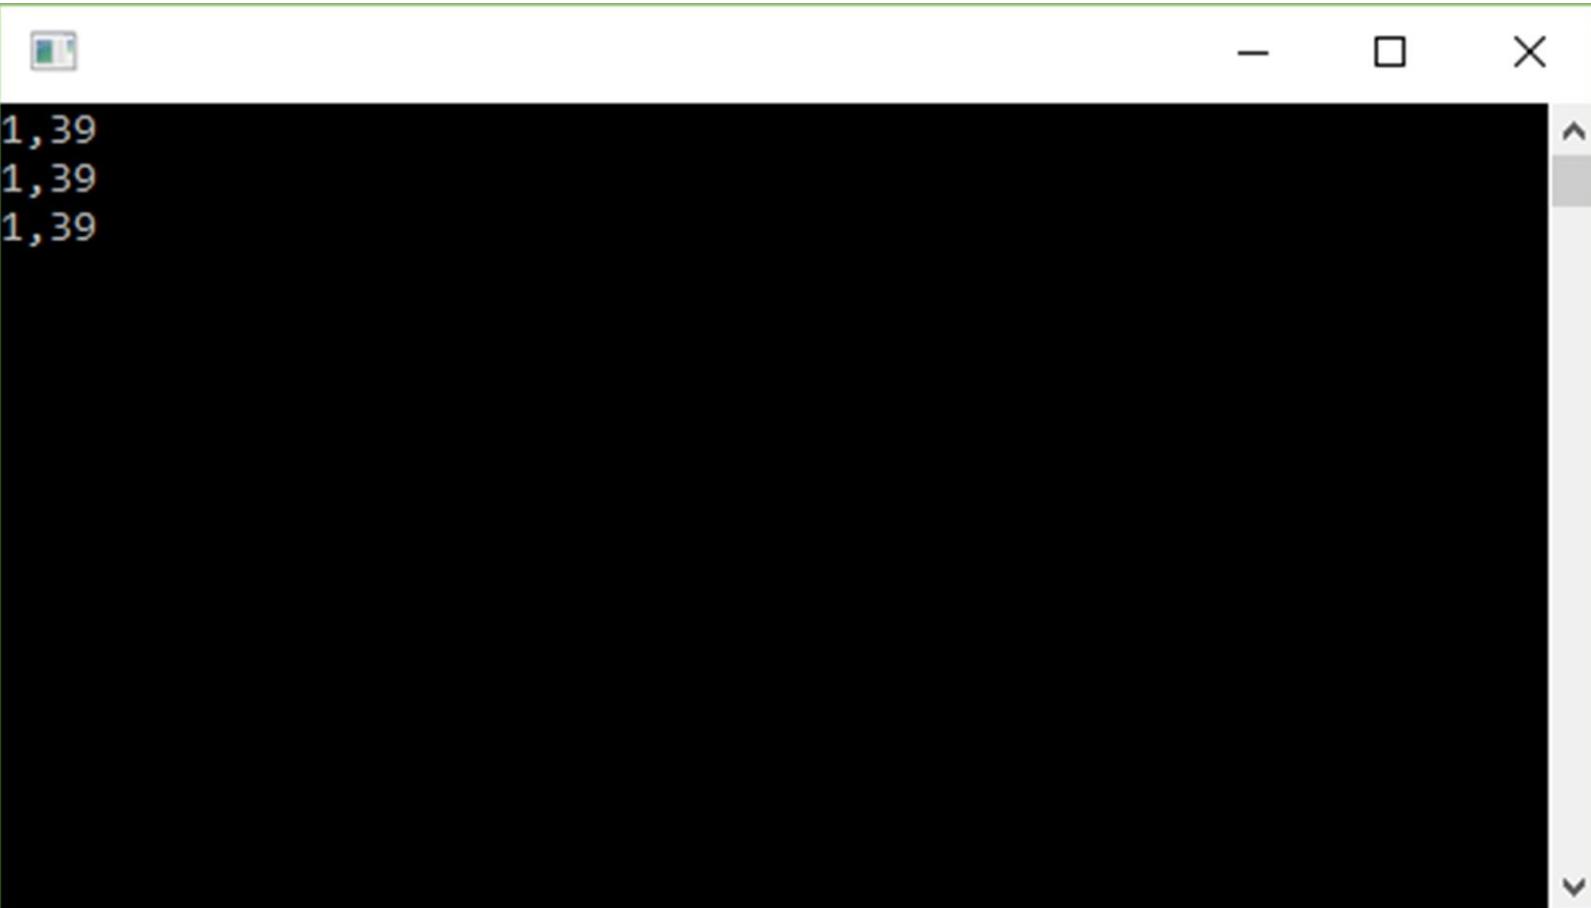

```
private void SetUniversalGravitationalConstant() {  
    UniversalGravitationalConstant = 6.6726 * Math.Pow(10, -11);  
}  
  
private double CalculateThrustToWeightRatio() {  
    // TWR = Ft/m.g > 1  
    return _EngineThrust / (_TotalShuttleMass * _LocalGravitationalAcceleration);  
}  
  
private double CalculateGravitationalAcceleration(double radius, double mass) {  
    return (UniversalGravitationalConstant * mass) / Math.Pow(radius, 2);  
}  
  
public double TWR() {  
    return Math.Round(CalculateThrustToWeightRatio(), 2);  
}
```

```
double thrust = 220; // kN  
double shuttleMass = 16.12; // t  
double gravitationalAccelerationEarth = 9.81;  
double earthMass = 5.9742 * Math.Pow(10, 24);  
double earthRadius = 6378100;  
double thrustToWeightRatio = 0;
```

```
LaunchShuttle NasaShuttle1 = new LaunchShuttle(thrust, <br/> shuttleMass,  
gravitationalAccelerationEarth); <br/> thrustToWeightRatio = NasaShuttle1.TWR(); <br/>  
Console.WriteLine(thrustToWeightRatio);
```

```
LaunchShuttle NasaShuttle2 = new LaunchShuttle(thrust, <br/> shuttleMass,  
LaunchShuttle.Planet.Earth); <br/> thrustToWeightRatio = NasaShuttle2.TWR(); <br/>  
Console.WriteLine(thrustToWeightRatio); <br/><br/> LaunchShuttle NasaShuttle3 = new  
LaunchShuttle(<br/> thrust, shuttleMass, earthMass, earthRadius); <br/>  
thrustToWeightRatio = NasaShuttle3.TWR(); <br/>  
Console.WriteLine(thrustToWeightRatio); <br/><br/> Console.Read();
```

9. If you run your console application, you will see that the same value is returned for the TWR. The value indicates that a shuttle weighing 16.12 tons with a rocket that puts out 220 kilonewtons of thrust will be able to lift off the surface of the Earth (if only just):

The screenshot shows a standard Windows command-line interface (CMD) window. The title bar is visible at the top. The main area of the window contains three lines of text, each showing the value '1,39'. The text is white on a black background, and the window has a standard window frame with minimize, maximize, and close buttons.

```
1,39  
1,39  
1,39
```

# How it works...

The class uses the scoping rules to hide certain functionality inside the class from the developer using the class. As mentioned earlier, the developer does not need to know how the calculations are done to return the value for the TWR. This all aids in making the class more useful and easy to implement. Here is a list of the various scopes available in C# along with their uses:

- `public`: This is used with variables, properties, types, and methods and is visible anywhere.
- `private`: This is used with variables, properties, types, and methods and is visible only in the block where they are defined.
- `protected`: This is used with variables, properties, and methods. Don't think of this in terms of public or private. The protected scope is only visible inside the class in which it is used as well as in any inherited classes.
- `friend`: This is used with variables, properties, and methods and can only be used by code in the same project or assembly.
- `protectedFriend`: This is used with variables, properties, and methods and is a combination (as the name suggests) of the protected and friend scopes.

# Implementing polymorphism

Polymorphism is a concept that is quite easy to grasp once you have looked at and understood the other pillars of OOP. Polymorphism literally means that something can have many forms. This means that from a single interface, you can create multiple implementations thereof.

There are two subsections to this, namely, static and dynamic polymorphism. With **static polymorphism**, you are dealing with the overloading of methods and functions. You can use the same method, but perform many different tasks.

With **dynamic polymorphism**, you are dealing with the creation and implementation of abstract classes. These abstract classes act as a blueprint that tells you what a derived class should implement. The following section looks at both.

# Getting ready

We will begin by illustrating the use of an abstract class, which is an example of dynamic polymorphism. We will then create overloaded constructors as an example of static polymorphism.

```
public abstract class Shuttle {  
    public abstract double TWR();  
}  
  
public class NasaShuttle : Shuttle {  
}  
  
public class NasaShuttle : Shuttle {  
    public override double TWR() {  
        throw new NotImplementedException();  
    }  
}  
  
public class RoscosmosShuttle : Shuttle {  
}  
  
public class RoscosmosShuttle : Shuttle {  
    public override double TWR() {  
        throw new NotImplementedException();  
    }  
}  
  
public NasaShuttle(double engineThrust, double totalShuttleMass, double gravitationalAcceleration) {  
}  
public NasaShuttle(double engineThrust, double totalShuttleMass, double planetMass, double planetRadius) {  
}
```

# How it works...

Polymorphism is something you will easily be using already by simply applying good object-oriented principles to the design of your classes. With the abstract `shuttle` class, we saw that the class took on the shape of the `NasaShuttle` class and the `RoscosmosShuttle` class when it was used to derive those new classes from its abstraction. The constructor of the `NasaShuttle` class was then overridden to provide the same method name, but implemented using different signatures.

This is at the heart of polymorphism. Most likely, you have been using it without knowing about it.

# Single responsibility principle

When talking about SOLID principles, we will start off with the **single responsibility principle (SRP)**. Here, we are actually saying that a class has a specific task that it needs to fulfill and it should not do anything else.

# Getting ready

You will create a new class and write code to log an error to the database when an exception is thrown on adding more troops to the star ship, causing it to be over capacity. For this recipe, ensure that you have added `using System.Data;` and `using System.Data.SqlClient;` namespaces to your application.

```
public class Starship {  
    public void SetMaximumTroopCapacity(int capacity) {  
  
        try {  
            // Read current capacity and try to add more  
        } catch (Exception ex) {  
            string connectionString = "connection string goes here";  
            string sql = $"INSERT INTO tblLog (error, date) VALUES  
                ({ex.Message}, {GetDate()});";  
            using (SqlConnection con = new SqlConnection(connectionString)) {  
                SqlCommand cmd = new SqlCommand(sql);  
                cmd.CommandType = CommandType.Text;  
                cmd.Connection = con;  
                con.Open();  
                cmd.ExecuteNonQuery();  
            }  
            throw ex;  
        }  
    }  
}
```

# How it works...

If you have code that looks like the preceding one, you are in contravention of the SRP. The `StarShip` class is no longer responsible for just itself and things that have to do with star ships. It now has to fulfill the role of logging errors to the database too. You see the problem here is that the database-logging code does not belong in the `catch` clause of the `setMaximumTroopCapacity` method. A better approach would be to create a separate `DatabaseLogging` class with methods to create connections and write exceptions to the appropriate log table. You will also find that you are going to have to write that logging code in multiple places (in every `catch` clause). If you are finding that you are repeating code (by copying and pasting from other areas), you probably need to put that code into a common class, and you have likely broken the SRP rule.

# **Open/closed principle**

When creating classes, we need to ensure that the class prohibits any breaking modifications by needing to change internal code. We say that such a class is closed. If we need to change it somehow, we can do so by extending the class. This extensibility is where we say that the class is open for extensions.

# Getting ready

You will create a class that determines the skills of a trooper by looking at the class of trooper. We will show you the way many developers create such a class and the way it can be created using the open/closed principle.

```
public class StarTrooper <br/> { <br/><br/> }

public enum TrooperClass { Soldier, Medic, Scientist } <br/> List<string> TroopSkill;
<br/><br/> public List<string> GetSkills(TrooperClass troopClass) <br/> { <br/> switch
(troopClass) <br/> { <br/> case TrooperClass.Soldier: <br/> return TroopSkill = new
List<string>(new string[] {<br/> "Weaponry", "TacticalCombat", "HandToHandCombat"
}); <br/><br/> case TrooperClass.Medic: <br/> return TroopSkill = new List<string>(new
string[] {<br/> "CPR", "AdvancedLifeSupport" }); <br/><br/> case
TrooperClass.Scientist: <br/> return TroopSkill = new List<string>(new string[] {<br/>
"Chemistry", "MolecularDeconstruction", <br/> "QuarkTheory" }); <br/><br/> default:
<br/> return TroopSkill = new List<string>(new string[] {<br/> "none" }); <br/> } <br/>
}

public class Trooper <br/> { <br/> public virtual List<string> GetSkills() <br/> { <br/>
return new List<string>(new string[] { "none" }); <br/> } <br/> }

public class Soldier : Trooper <br/> { <br/> public override List<string> GetSkills()
<br/> { <br/> return new List<string>(new string[] { "Weaponry", <br/>
"TacticalCombat", "HandToHandCombat" }); <br/> } <br/> } <br/><br/> public class
Medic : Trooper <br/> { <br/> public override List<string> GetSkills() <br/> { <br/>
return new List<string>(new string[] { <br/> "CPR", "AdvancedLifeSupport" }); <br/>
} <br/><br/> public class Scientist : Trooper <br/> { <br/> public override
List<string> GetSkills() <br/> { <br/> return new List<string>(new string[] {
"Chemistry", <br/> "MolecularDeconstruction", "QuarkTheory" }); <br/> } <br/> }

public class Engineer : Trooper <br/> { <br/> public override List<string> GetSkills()
<br/> { <br/> return new List<string>(new string[] { <br/> "Construction", "Demolition"
}); <br/> } <br/> }
```

# How it works...

The classes derived from the `Trooper` class are extensions of the `Trooper` class. We can say that each class is closed, because modifying it does not necessitate changing the original code. The `Trooper` class is also extensible because we have been able to easily extend the class by creating derived classes from it.

Another byproduct of this design is smaller, more manageable code that is easier to read and understand.

# Exception handling

Exception handling is something that you as a developer need to be aware of, and you must also be very good at discerning what information to display to the end user and what information to log. Believe it or not, writing good error messages is harder than it looks. Too much information displayed to the user might instill a sense of distrust in the software. Too little information logged for debugging purposes is also not useful at all to the poor soul that needs to fix the error. This is why you need to have an **exception handling strategy**.

A nice rule of thumb is to display a message to the user stating that something went wrong, but that a notification has been sent to support personnel. Think of Google, Dropbox, Twitter (remember the blue whale?), and other big companies. Humorous error pages with a little robot whose arm fell off, or a popular meme displayed to the user is far better than a threatening error page with a full stack trace and red text. It is something that momentarily takes the user's mind off a frustrating situation. Most importantly of all, it lets you save face.

So let's start off by looking at exception filters. These have been around for some time. Visual Basic.NET (VB.NET) and F# devs have had this functionality for a while. It was introduced in C# 6.0 and does more than meets the eye. At first glance, it looks as if exception filters merely specify a condition when an exception needs to be caught. This is, after all, what the name *exception filter* implies. Upon closer inspection, however, we see that exception filters act as more than just syntactical sugar.

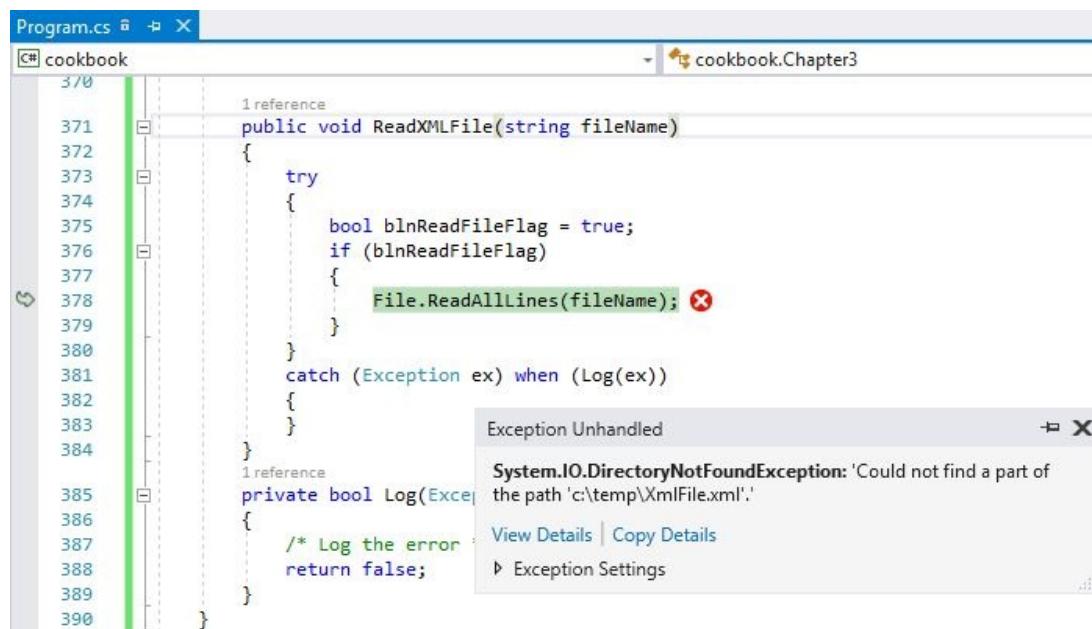

```
using System.IO;
```

```
public void ReadXMLFile(string fileName){  
    try{  
        bool blnReadFileFlag = true;  
        if (blnReadFileFlag){  
            File.ReadAllLines(fileName);  
        }  
    } catch (Exception ex){  
        Log(ex);  
        throw;  
    }  
}  
private void Log(Exception e){  
    /* Log the error */  
}
```

```
Chapter3 ch3 = new Chapter3();  
string File = @"c:\temp\XmlFile.xml";  
ch3.ReadXMLFile(File);
```

```
public void ReadXMLFile(string fileName){  
    try{  
        bool blnReadFileFlag = true;  
        if (blnReadFileFlag){  
            File.ReadAllLines(fileName);  
        }  
    } catch (Exception ex) when (Log(ex)){  
    }  
    private bool Log(Exception e){  
        /* Log the error */  
        return false;  
    }  
}
```

6. Running the console application again, Visual Studio will break on the actual line of code that caused the exception:

7. More importantly, the value of `blnReadFileFlag` is still in scope. This is because exception filters can see the state of the stack at the point where the exception occurred instead of where the exception was handled. Looking at the locals window in Visual Studio, you will see that the variables are still in scope at the point where the exception occurred:

Watch 1

Name	Value
blnReadFileFlag	true

Locals Watch 1

# How it works...

Imagine being able to view the exception information in a log file with all the local variable values available. Another interesting point to note is the return `false` statement in the `Log(ex)` method. Using this method to log the error and return `false` will allow the application to continue and have the exception handled elsewhere. As you know, catching `Exception ex` will catch everything. By returning `false`, the exception filter doesn't run into the `catch` statement, and more specific `catch` exceptions (for example, `catch (FileNotFoundException ex)` after our `catch (Exception ex)` statement) can be used to handle specific errors. Normally, when catching exceptions, `FileNotFoundException` will never be caught in the following code example:

```
catch (Exception ex)
{
}
catch (FileNotFoundException ex)
{
}
```

This is because the order of the exceptions being caught is wrong. Traditionally, developers must catch exceptions in their order of specificity, which means that `FileNotFoundException` is more specific than `Exception` and must, therefore, be placed before `catch (Exception ex)`. With exception filters that call a `false` returning method, we can inspect and log an exception accurately:

```
catch (Exception ex) when (Log(ex))
{
}
catch (FileNotFoundException ex)
{
}
```

The preceding code will catch all exceptions, and in doing so, log the exception accurately but not step into the exception handler because the `Log(ex)` method returns `false`. Another implementation of exception filters is that they can allow developers to retry code in the event of a failure. You might not specifically want to catch the first exception, but implement a type of timeout element to your method. When the error counter has reached the maximum iterations, you can catch and handle the exception. You can see an example of catching an exception based on a `try` clauses' count here:

```
public void TryReadXMLFile(string fileName)
{
    bool blnFileRead = false;
    do
    {
        int iTryCount = 0;
        try
        {
            bool blnReadFileFlag = true;
            if (blnReadFileFlag)
                File.ReadAllLines(fileName);
        }
        catch (Exception ex) when (RetryRead(ex, iTryCount++) == true)
        {
        }
    } while (!blnFileRead);
}

private bool RetryRead(Exception e, int tryCount)
{
    bool blnThrowEx = tryCount <= 10 ? blnThrowEx =
        false : blnThrowEx = true;
```

```
| /* Log the error if blnThrowEx = false */  
| return blnThrowEx;  
}
```

Exception filtering is a very useful and extremely powerful way to handle exceptions in your code. The behind-the-scenes workings of exception filters are not as immediately obvious as one might imagine, but here lies the actual power of exception filters.

# Code Analyzers in Visual Studio

In this chapter we will take a look at code analyzers and how they can assist developers to write better code. We will cover the following topics:

- Finding and installing analyzers
- Creating a code analyzer
- Creating a custom code analyzer
- Deploying your code analyzer within your organization only

# Introduction

With effect from Visual Studio 2015, developers have had the ability to create custom code analyzers that are specific to their project or their development team. Some development teams have a set of standards that they need to adhere to. Perhaps you are an indie developer and you would like to make your code conform to certain best practices. It doesn't really matter what your reason is; code analyzers open doors for developers.

You can be sure that the code you or your team ships measures up to your specific set of code quality standards. There are several code analyzers that can be downloaded from GitHub. We will be looking at one of those called CodeCracker for C#.

# Finding and installing analyzers

There are quite a few code analyzers on GitHub. A quick search returns 28 possible C# code analyzers out of 72 repository results. A few of these seem to be student projects. Check those out too; there is some very clever code in some of them. As for this recipe, we will be working with CodeCracker for C# to demonstrate how to install an analyzer from a NuGet package.

The screenshot shows a GitHub search interface. In the top right corner, there is a search bar containing the query "c# code analyzers". To the right of the search bar are icons for notifications, a plus sign, and a user profile. Below the search bar, the text "We've found 72 repository results" is displayed, followed by a "Sort: Best match" dropdown menu. On the left side, there is a sidebar with sections for "Repositories" (72), "Code" (367,665), "Commits" (31,187), "Issues" (1,163), "Wikis" (489), and "Users". Below this, there is a "Languages" section showing counts for C# (28), C++ (16), C (6), and Python (5). The main content area displays two repository results. The first result is "code-cracker/code-cracker", described as "An analyzer library for C# and VB that uses Roslyn to produce refactorings, code analysis, and other niceties." It has 655 stars, 216 forks, and was updated 7 days ago. The second result is "DustinCampbell/CSharpEssentials", described as "C# Essentials is a collection of Roslyn diagnostic analyzers, code fixes and refactorings that make it easy to work w...". It has 134 stars, 25 forks, and was updated on Jun 7, 2016.

# Getting ready

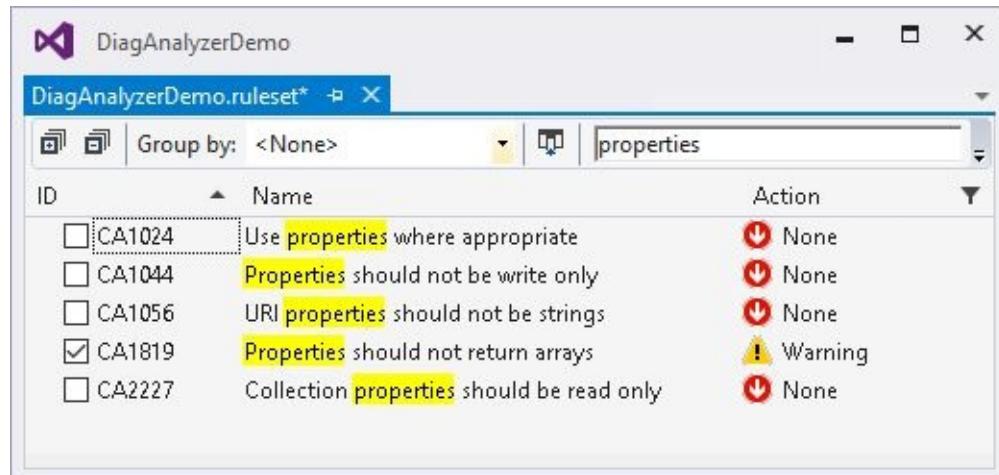

All that you will be doing is downloading a NuGet package for your project. Other than that, there is nothing you specifically need to do in order to get ready.

```

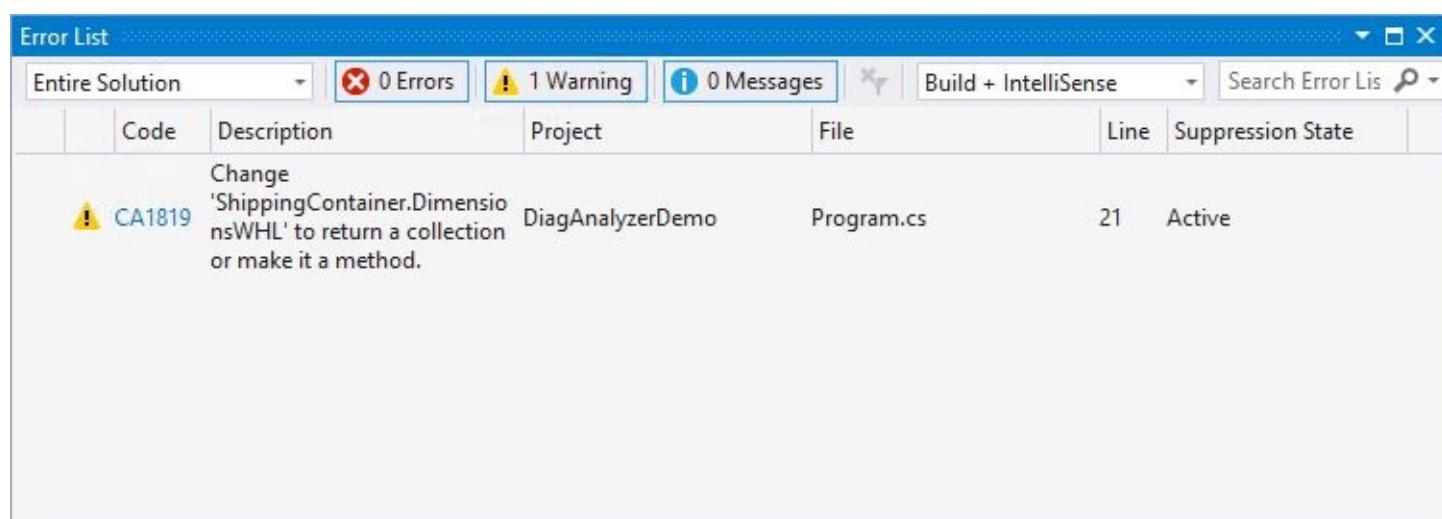

public class ShippingContainer<br/> {<br/> public int Width { get; set; }<br/> public int Height { get; set; }<br/> public int Length { get; set; }<br/> public int[] DimensionsWHL { get; set; }<br/> public ShippingContainer(int width, int height, int length)<br/> {<br/> Width = width;<br/> Height = height;<br/> Length = length;<br/><br/> DimensionsWHL = new int[] { width, height, length };<br/> }

```

13. Return back to the analyzers screen and search for the word properties. You will see an analyzer returned called CA1819, which specifies that a property should never return an array. The Action is changed to Warning, but you can change this to Error should you wish by clicking on the word Warning under the Action column and selecting Error.

14. Save the changes and go and build your console application. You will see that the warning for the code analyzer CA1819 is displayed in the Error List. If you had changed the action to Error, the build would have broken with that error.

# How it works...

Code analyzers can provide you with a lot of functionality and assist developers in writing good code by avoiding common bad coding practices and enforcing specific team guidelines. Each code analyzer can be set to a different severity, with the most severe actually breaking the build. Keeping code analyzers under the references in your projects allows you to check it in to source control; this is evaluated whenever you build your project. You can however also store analyzers on a per-machine basis. These analyzers will be for personal code improvement, prompts, and personal use.

Code analyzers are perfect for modern day developers because they are under the control of the developer and integrate easily into Visual Studio.

# Creating a code analyzer

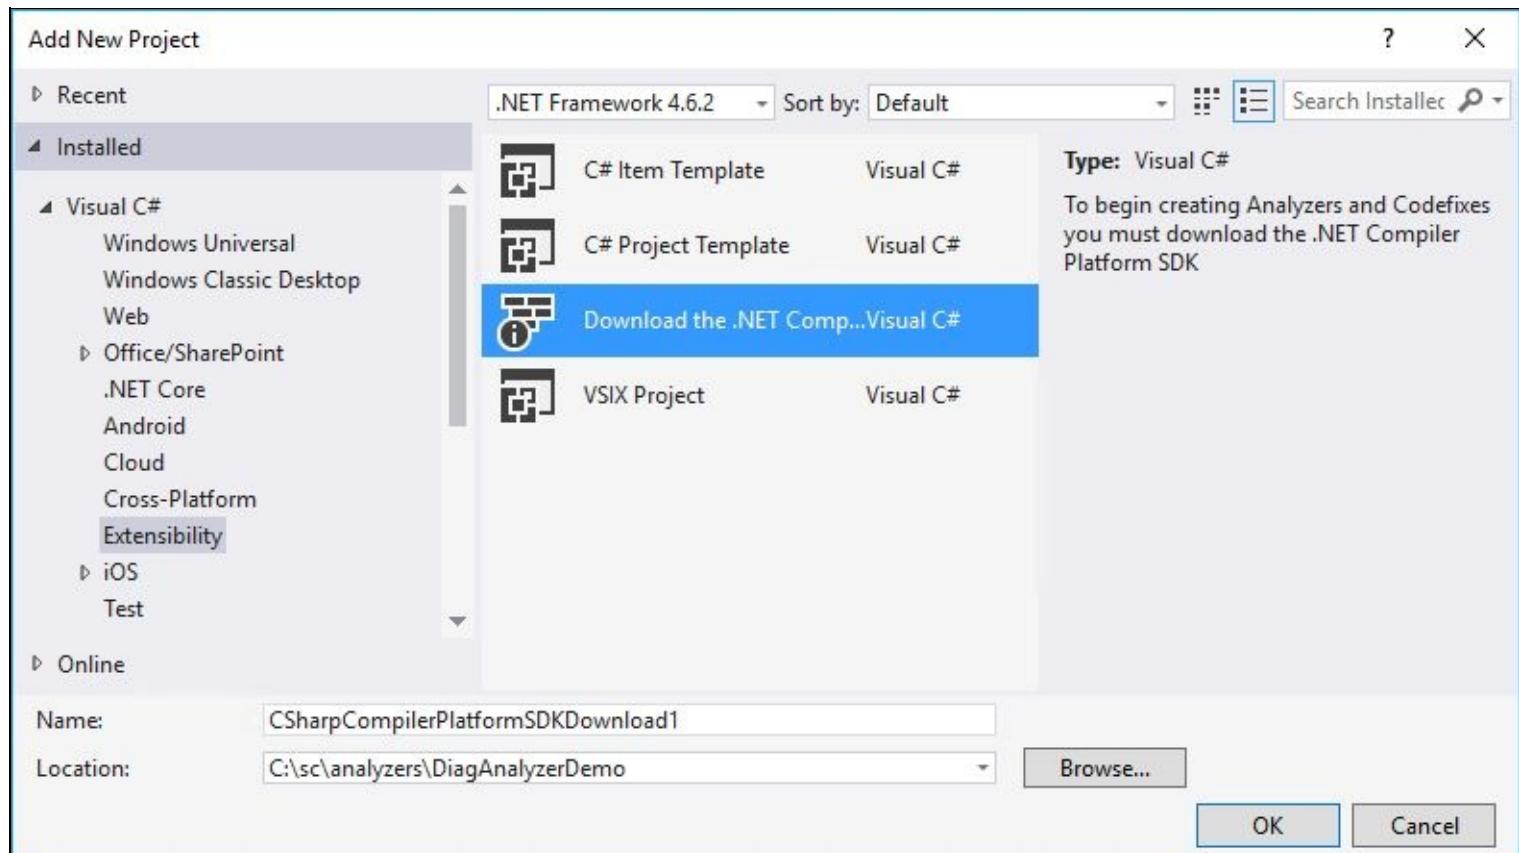

Some of you might already see the benefit of creating your own code analyzer. Being able to control certain design implementations and coding standards specific to your team is invaluable. This is especially true for new developers joining your team. I remember when I started working for a company a couple of years back; the development manager gave me a document of code standards that I needed to adhere to. At the time this was great. It showed me that they cared about code standards. Back then, of course, developers didn't have code analyzers. It was however quite a challenge keeping track of all the standards that I needed to implement. This was especially true for the specific code standards that the company implemented.

# Getting ready

Before you can create your own code analyzer, you need to ensure that you have installed the .NET Compiler Platform SDK. To do this, perform the following steps:

1. Add a new project to your solution and click on Extensibility. Select Download the .NET Compiler Platform SDK and click OK.

2. This will actually create a project with an index file. The page that opens will provide a download to the .NET Compiler Platform SDK. Click on that to start the download.

C:\sc\analyzers\DiagAnalyzerDemo\CSharpCompilerPlatformSDKDownload1\index.html

URL: C:\sc\analyzers\DiagAnalyzerDemo\CSharpCompilerPlatformSDKDownload1\index.html

## About .NET Compiler Platform

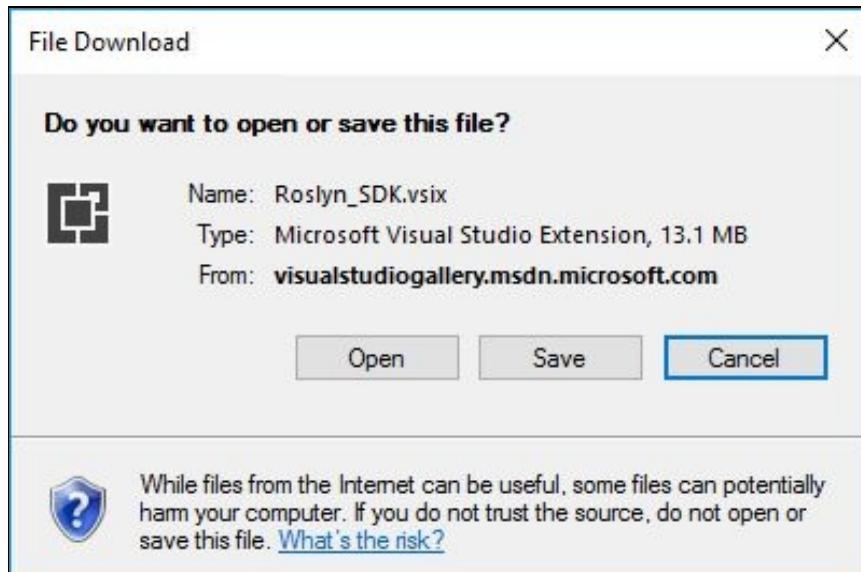

# .NET Compiler Platform SDK Templates

Provides three Visual Studio project templates for both C# and Visual Basic that enable the creation of Analyzers, CodeFixes, and stand-alone analysis tools.

[Download .NET Compiler Platform SDK Templates »](#)

Note: The project that contains this page only provides instructions to install the required templates.

3. Just save the downloaded file to a directory on your hard drive. Then you should close down Visual Studio before clicking on the VSIX file.

4. The .NET Compiler Platform SDK installer will now start and allow you to select the instance of Visual Studio to install to.

When the installation is complete, restart Visual Studio again.

**Installation Complete**

Your extension has been successfully installed. Please close and restart all target application instances for changes to take effect.

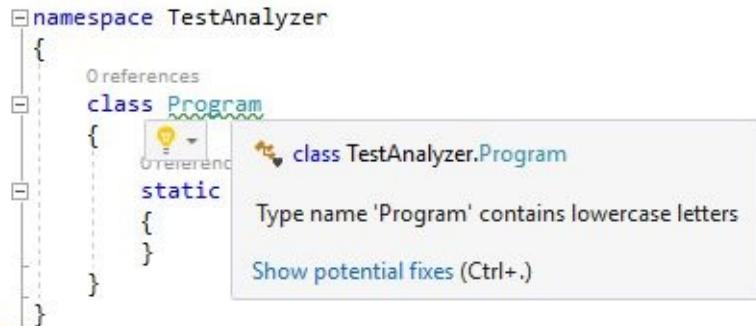

[View Install Log](#)[Close](#)

```

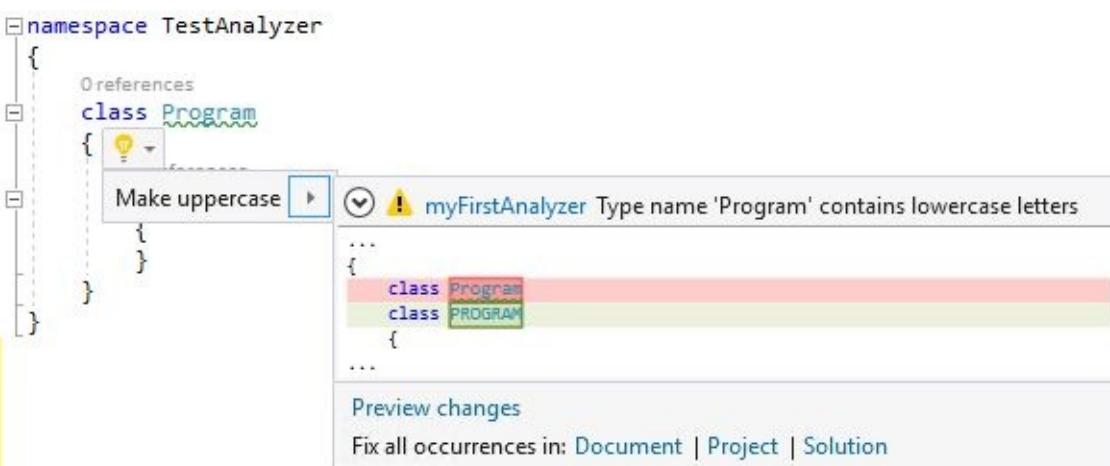

private static void AnalyzeSymbol(<br/> SymbolAnalysisContext context){<br/> //
TODO: Replace the following code with your own <br/> analysis, generating Diagnostic
objects for any <br/> issues you find<br/> var namedTypeSymbol =
(INamedTypeSymbol)context.Symbol;<br/><br/> // Find just those named type symbols
with names <br/> containing lowercase letters.<br/> if
(namedTypeSymbol.Name.ToCharArray().Any(char.IsLower))<br/> {<br/> // For all
such symbols, produce a diagnostic.<br/> var diagnostic = Diagnostic.Create(Rule, <br/>
namedTypeSymbol.Locations[0], namedTypeSymbol.Name);<br/><br/>
context.ReportDiagnostic(diagnostic);<br/> }<br/> }

```

4. Build your project and click on *F5* to start debugging. This will start a new instance of Visual Studio with its own settings. This means anything you change in this experimental instance of Visual Studio will not affect your current Visual Studio installation. You can open an existing project or create a new one. I simply created a console application. From the start, you will see that the `Program` class name is underlined. Hovering your cursor over this will display the Visual Studio lightbulb and tell you that the type name contains lowercase letters.

5. Clicking on *Ctrl + .* or on the Show potential fixes link in the tooltip will display the fixes you can apply to correct the error.

# How it works...

Code analyzers will check managed assemblies and report any information relevant. This can be any code that violates the programming and design rules in the *.NET Framework Design Guidelines*. The code analyzer will display the checks it performs as warning messages and if possible suggest a fix like we saw in the aforementioned recipe. To do this, code analyzers use rule sets created by Microsoft or a custom rule set you define to meet a specific need.

# Creating a custom code analyzer

The real magic of code analyzers come to the fore when you create one to suit a specific need. What would qualify as a specific need? Well anything that is specific to your own business requirements that is not covered in the out-of-the-box analyzers. Don't get me wrong; the existing analyzers that are available to developers really cover a lot of good programming practices. Just take a look on GitHub by searching for C# code analyzers.

Sometimes, however, you might have a case where something is more suited to your workflow or the way your company does business.

An example of this could be to ensure that comments on all public methods include more information than just the standard `<summary></summary>` and parameter information (if any). You might want to include an additional tag with the internal task ID, for example (think Jira here). Another example is making sure that a created class conforms to a certain XML structure. Are you developing software that writes warehouse stock information to a database? Do you use non-stocked parts? How do you validate non-stocked from stocked parts in code? Code analyzers can provide a solution here.

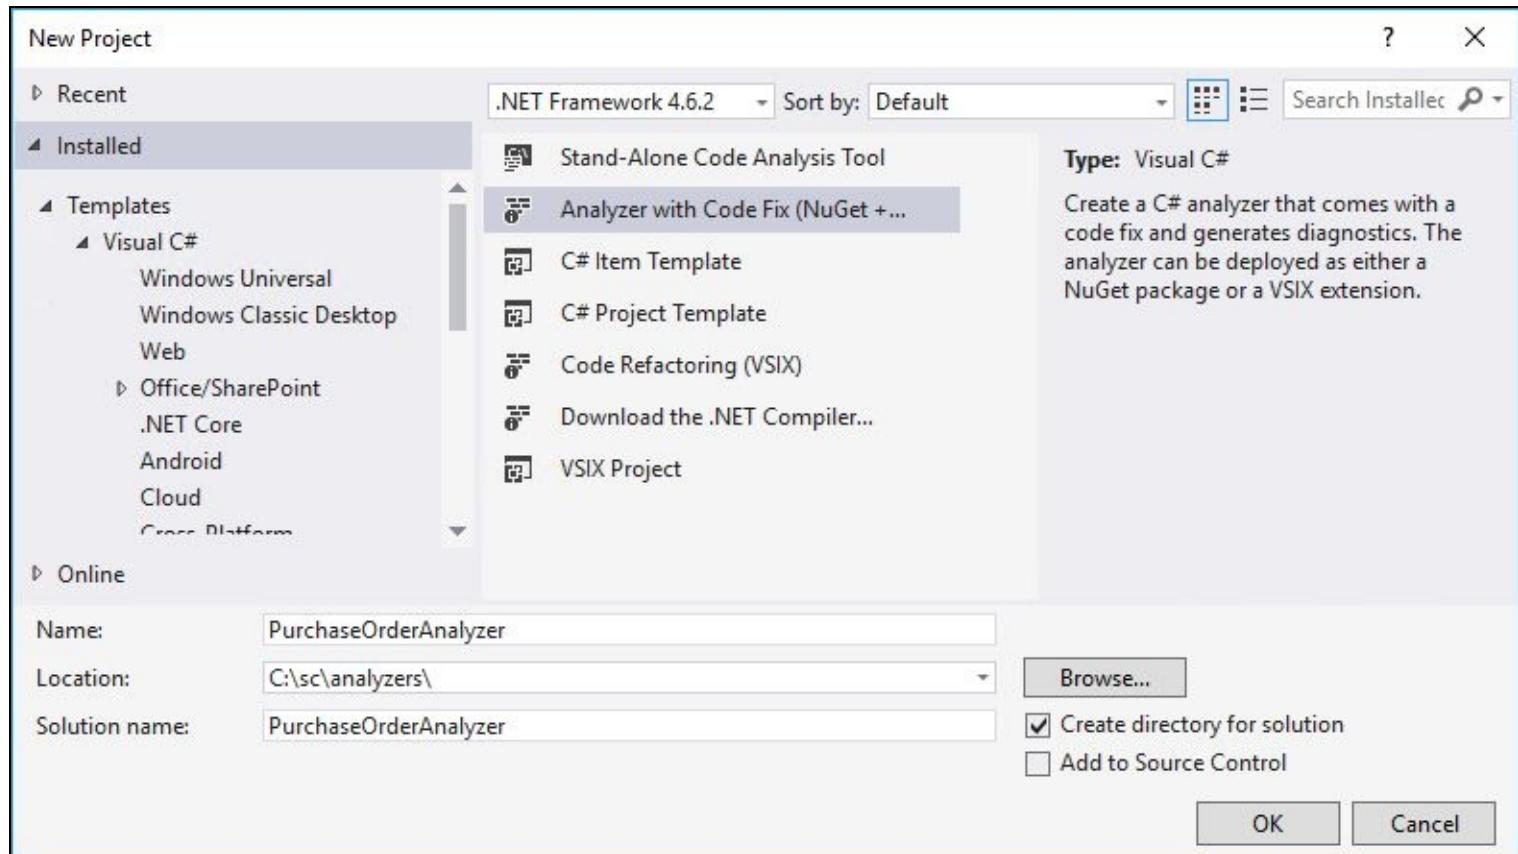

The preceding examples are perhaps rather unique and not applicable to you or your needs at all, but that is the beauty of code analyzers. You can create them to suit your requirements. Let's take a look at a very simple example. Assume that developers in your organization need to use a specific code library. This code library is a collection of frequently used code and is well maintained. It is included in a Visual Studio template that developers use when creating new projects. We need to ensure that, if a developer creates a specific class (for purchase orders or sales orders), it implements a specific interface. The interfaces exist in the template, but the classes do not. This is because the applications will not always be using sales or purchase orders. The interface is to enable the receipt of sales and purchase orders and is called `IReceivable`.

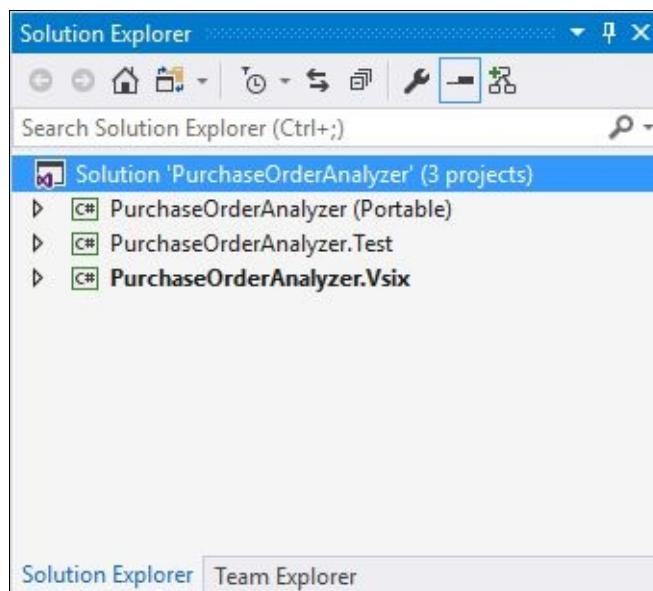

# Getting ready

Perform the following steps:

1. Create a new Visual Studio project and call it PurchaseOrderAnalyzer.

2. Ensure that the following projects are created by default in your solution.

```
public const string DiagnosticId = "PurchaseOrderAnalyzer";<br/><br/> public enum  
ClassTypesToCheck { PurchaseOrder, SalesOrder }<br/> public enum  
MandatoryInterfaces { IReceiptable }<br/><br/> private static readonly LocalizableString  
Title = <br/> "Interface Implementation Available"; <br/> private static readonly  
LocalizableString <br/> MessageFormat = "IReceiptable Interface not Implemented";  
<br/> private static readonly LocalizableString Description = <br/> "You need to  
implement the IReceiptable interface"; <br/> private const string Category = "Naming";  
<br/><br/> private static DiagnosticDescriptor Rule = new <br/>  
DiagnosticDescriptor(DiagnosticId, Title, MessageFormat, <br/> Category,  
DiagnosticSeverity.Warning, <br/> isEnabledByDefault: true, description: Description);  
  
public override void Initialize(AnalysisContext context)<br/> {<br/>  
context.RegisterSymbolAction>AnalyzeSymbol, <br/> SymbolKind.NamedType);<br/> }  
  
private static void AnalyzeSymbol(SymbolAnalysisContext context)<br/> {<br/><br/> }  
  
bool blnInterfaceImplemented = false;<br/> if (!context.Symbol.IsAbstract)<br/> {<br/>  
<br/> }  
  
var namedTypeSymbol = (INamedTypeSymbol)context.Symbol;<br/> List<string>  
classesToCheck = Enum.GetNames(<br/> typeof(ClassTypesToCheck)).ToList();<br/>  
<br/> if (classesToCheck.Any(s => s.Equals(<br/> namedTypeSymbol.Name,  
StringComparison.OrdinalIgnoreCase)))<br/> {<br/><br/> }  
  
string interfaceName = nameof(<br/> MandatoryInterfaces.IReceiptable);<br/><br/> if  
(namedTypeSymbol.AllInterfaces.Any(s => s.Name.Equals(<br/> interfaceName,  
StringComparison.OrdinalIgnoreCase)))<br/> {<br/> blnInterfaceImplemented = true;  
<br/> }<br/><br/> if (!blnInterfaceImplemented)<br/> {<br/> // Produce a diagnostic.  
<br/> var diagnostic = Diagnostic.Create(Rule, <br/> namedTypeSymbol.Locations[0],  
namedTypeSymbol.Name);<br/> context.ReportDiagnostic(diagnostic);<br/> }  
  
private static void AnalyzeSymbol(SymbolAnalysisContext context)<br/> {<br/> bool  
blnInterfaceImplemented = false;<br/> if (!context.Symbol.IsAbstract)<br/> {<br/> var  
namedTypeSymbol = (INamedTypeSymbol)context.Symbol;<br/> List<string>  
classesToCheck = Enum.GetNames(<br/> typeof(ClassTypesToCheck)).ToList();<br/>  
<br/> if (classesToCheck.Any(s => s.Equals(namedTypeSymbol.Name, <br/>  
StringComparison.OrdinalIgnoreCase)))<br/> {<br/> string interfaceName =  
nameof(<br/> MandatoryInterfaces.IReceiptable);<br/><br/> if  
(namedTypeSymbol.AllInterfaces.Any(s => s.Name.Equals(<br/> interfaceName,  
StringComparison.OrdinalIgnoreCase)))<br/> {<br/> blnInterfaceImplemented = true;
```

```

<br/> }<br/><br/> if (!blnInterfaceImplemented)<br/> {<br/> // Produce a diagnostic.
<br/> var diagnostic = Diagnostic.Create(Rule, <br/> namedTypeSymbol.Locations[0],
namedTypeSymbol.Name);<br/> context.ReportDiagnostic(diagnostic);<br/> }<br/>
<br/> }<br/> }

private const string title = "Implement IReceiptable";

public sealed override async Task RegisterCodeFixesAsync(<br/> CodeFixContext
context)<br/> {<br/> var root = await context.Document.GetSyntaxRootAsync(<br/>
context.CancellationToken).ConfigureAwait(false);<br/><br/> var diagnostic =
context.Diagnostics.First();<br/> var diagnosticSpan = diagnostic.Location.SourceSpan;
<br/><br/> // Find the type declaration identified by the diagnostic.<br/> var declaration =
root.FindToken(diagnosticSpan.Start)<br/> .Parent.AncestorsAndSelf().OfType<br/>
<TypeDeclarationSyntax>().First();<br/><br/> // Register a code action that will invoke
the fix.<br/> context.RegisterCodeFix(<br/> CodeAction.Create(<br/> title: title,<br/>
createChangedSolution: c => <br/>
ImplementRequiredInterfaceAsync(context.Document, <br/> declaration, c),<br/>
equivalenceKey: title),<br/> diagnostic);<br/> }

private async Task<Solution> ImplementRequiredInterfaceAsync(<br/> Document
document, TypeDeclarationSyntax typeDecl, <br/> CancellationToken cancellationToken)
<br/> {<br/> // Get the text of the PurchaseOrder class and return one <br/>
implementing the IPurchaseOrder interface<br/> var identifierToken =
typeDecl.Identifier;<br/><br/> var newName = $"{{identifierToken.Text}} : IReceiptable";
<br/><br/> // Get the symbol representing the type to be renamed.<br/> var
semanticModel = await document.GetSemanticModelAsync(<br/> cancellationToken);
<br/> var typeSymbol = semanticModel.GetDeclaredSymbol(<br/> typeDecl,
cancellationToken);<br/><br/> // Produce a new solution that has all references to <br/>
that type renamed, including the declaration.<br/> var originalSolution =
document.Project.Solution;<br/> var optionSet = originalSolution.Workspace.Options;
<br/> var newSolution = await Renamer.RenameSymbolAsync(<br/>
document.Project.Solution, typeSymbol, newName, <br/> optionSet,
cancellationToken).ConfigureAwait(false);<br/><br/> return newSolution;<br/> }

interface IReceiptable<br/> {<br/> void MarkAsReceived(int orderNumber);<br/> }

public class PurchaseOrder <br/> {<br/><br/> }

public class PurchaseOrder : IReceiptable <br/> {<br/><br/> }

```

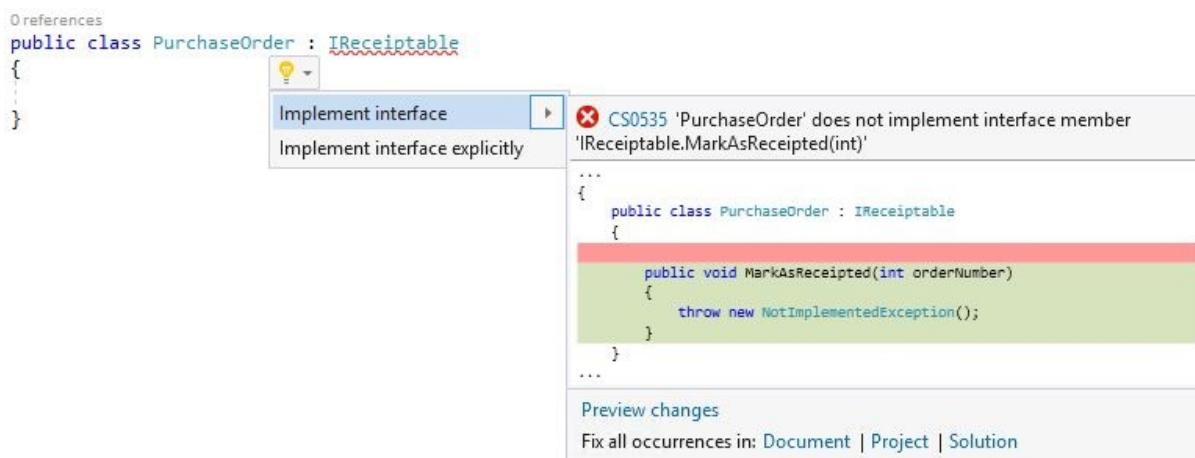

19. Once the code fix has been applied, you will see that the squiggly line under the class

name has disappeared. As expected, Visual Studio is now telling us that we need to implement the interface member `IReceiptable.MarkAsReceived(int)` by underlining the interface name `IReceiptable` with a red squiggly line.

A screenshot of the Visual Studio IDE showing the `PurchaseOrder.cs` file. The code defines a class `PurchaseOrder` that implements the `IReceiptable` interface. The interface name `IReceiptable` is underlined with a red squiggle, indicating a missing implementation. The code editor shows the following:

```
6
7  namespace PurchaseOrderConsole
8  {
9      public class PurchaseOrder : IReceiptable
10     {
11     }
12  }
```

20. Hovering over the `IReceiptable` interface name, you will see the lightbulb the code fix. This is the standard Visual Studio analyzer at work here.

21. Clicking on the fix to be applied implements the `IReceiptable` member and the `PurchaseOrder` class is correctly defined in the code.

A screenshot of the Visual Studio IDE showing the `PurchaseOrder.cs` file after applying the code fix. The `IReceiptable` interface implementation is now present in the class. The code editor shows the following:

```
7  namespace PurchaseOrderConsole
8  {
9      public class PurchaseOrder : IReceiptable
10     {
11         public void MarkAsReceived(int orderNumber)
12         {
13             throw new NotImplementedException();
14         }
15     }
16 }
```

# How it works...

The example in this recipe does not even begin to scratch the surface of what is possible with code analyzers. A great way to learn what is possible is to have a look at some of the code analyzers on GitHub. View the code and start writing your own code analyzers. As with most concepts in programming, the only way to learn this is to write the code. There is a wealth of information available on the Internet. A word of advice, though: before you start writing your code analyzers, take a look to see if there isn't an analyzer that already does what you need (or is close to doing what you need).

For example, if you need to ensure method comments include additional information, try to find an analyzer that already does something similar. If you find an analyzer that checks to see if public methods have comments, for example, you could easily retrofit this analyzer to suit your own needs. The best way to learn is to do, but everybody needs a starting point. Standing on the shoulders of others is part of learning new programming concepts.

# **Deploying your code analyzer within your organization only**

Code analyzers are a fantastic method to check and correct code automatically. Sometimes, however, the analyzers you create will not be suitable for public consumption as they might contain proprietary information. With NuGet, you can create private repositories and share these with colleagues. You can use a shared location on a company server, for example, and easily manage NuGet packages from there.

# Getting ready

Ensure that you have a shared location accessible to all developers in your organization. This can be anywhere your network administrator has provided for shared file access. You will probably want to restrict the access of these packages to developers only. A nice solution is to create a storage account on Azure to share the NuGet packages to. This is the approach I followed here using a fictitious company I have called Acme Corporation.

I will not go through setting up a storage account on Azure, but I will talk about accessing it from your local machine.

*I encourage you and your organization to consider using Azure. I will not expand much on the benefits of using Azure other than to say that it is an incredible time-saver. If I want to test a specific feature of an application on a particular OS, within minutes I am able to spin up a VM and connect to it via a remote desktop. It is immediately ready to use.*

After you have created your storage account on Azure, you will find the access keys on the Access keys tab.

1. Make a note of the keys and the Storage account name.

The screenshot shows the Microsoft Azure Storage accounts interface. The top navigation bar says "Microsoft Azure" and "Storage accounts > acmenuget - Access keys". On the left, there's a sidebar with icons for Overview, Activity log, Access control (IAM), Tags, Diagnose and solve problems, SETTINGS (with "Access keys" highlighted in blue), Configuration, and a plus sign. The main content area has a search bar at the top. Below it, there's a text block about using access keys for authentication. Under "Storage account name", it says "acmenuget". There's a table with two rows:

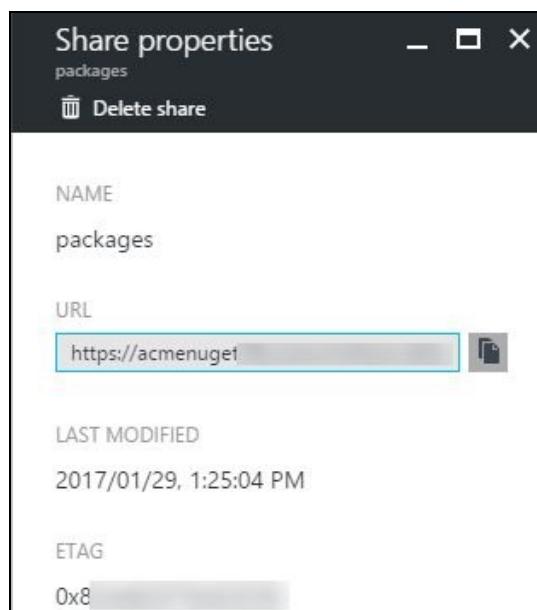

NAME	KEY
key1	mC1
key2	xyoC

Each key row has a copy icon and a refresh icon.

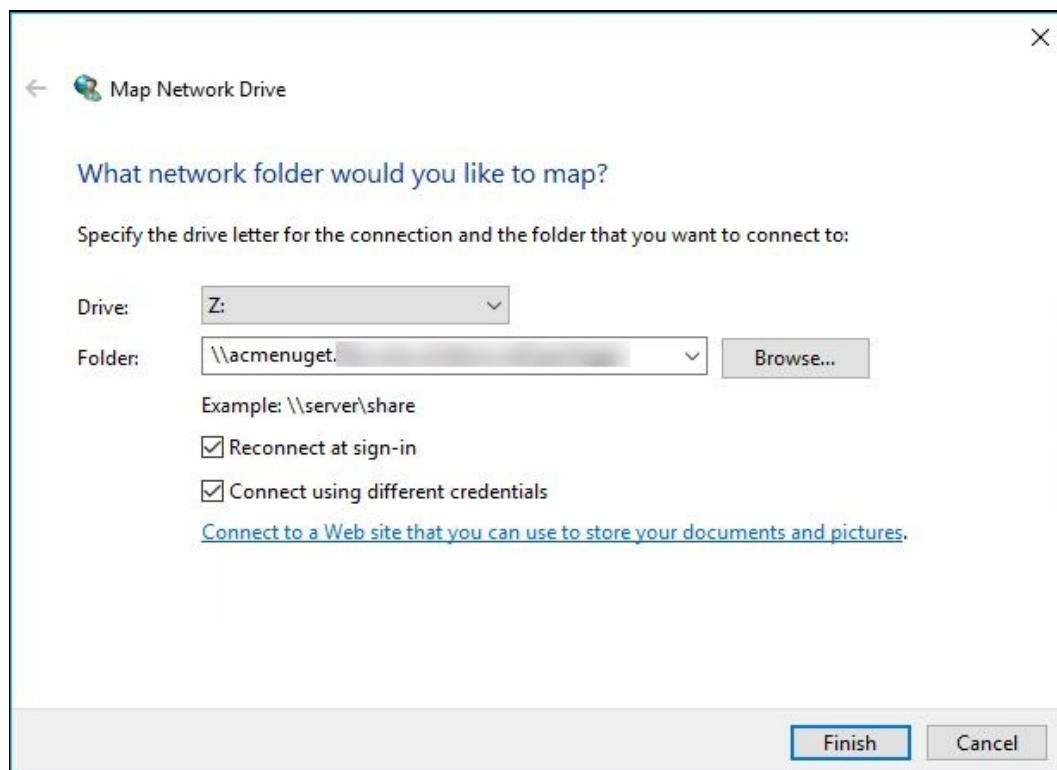

2. I also just created a File service called packages. To get here, click on Overview. Then, under the Services heading, click on Files. On the File service window, select packages and view the property information for the file share.

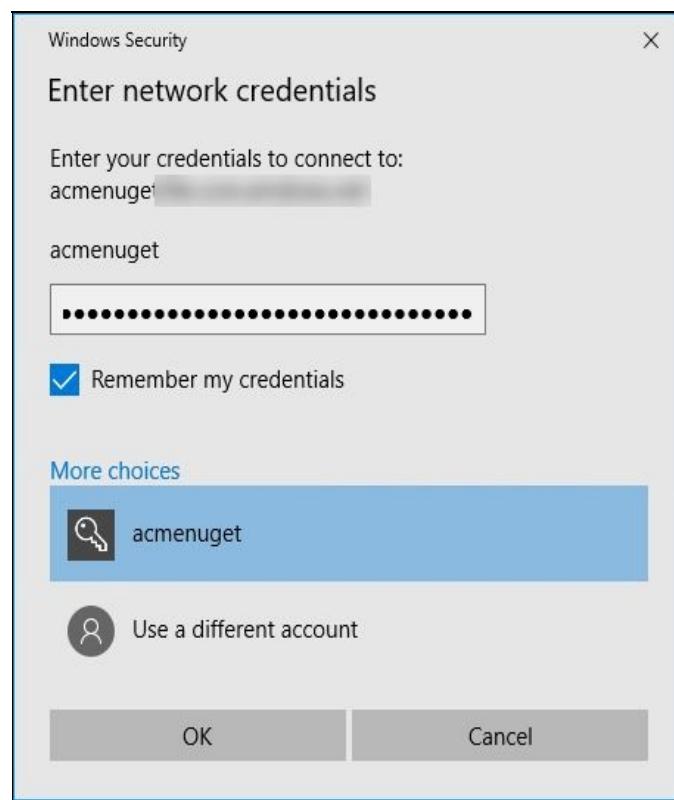

*Your storage account might differ from the examples in this book, depending on what you called it.*

3. Make a note of the URL specified in the properties. Using the URL, map a network drive by changing the https:// part to \\ and any subsequent / to \ in the path.

4. Add this path to the Folder textbox and ensure that you have checked Connect using different credentials.

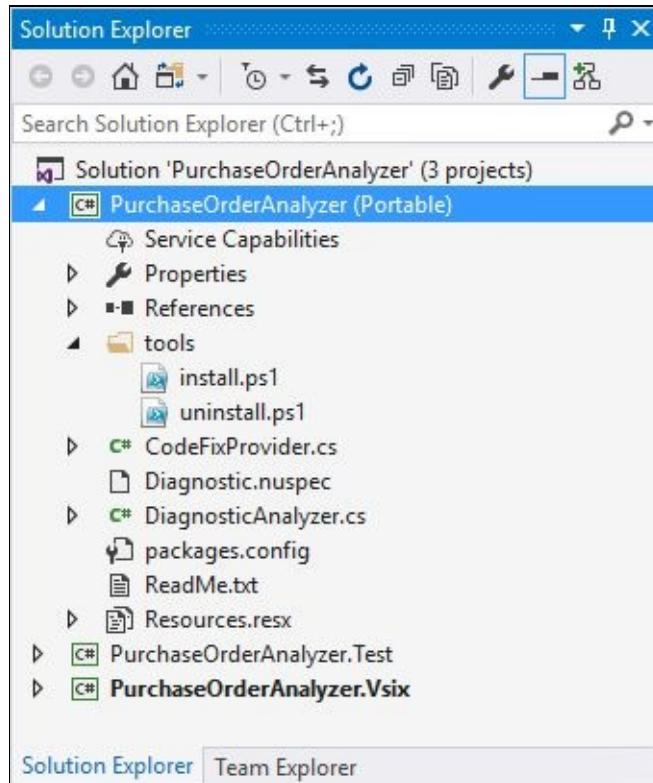

Use the storage account name as the username and one of the keys as the password. You now have a network drive mapped to your Azure Storage account.

# How to do it...

1. Have a look at the `PurchaseOrderAnalyzer` project we created. You will see that there is a `tools` folder containing two PowerShell scripts called `install.ps1` and `uninstall.ps1`. It is here that you can specify any installation-specific resources or actions to take when uninstalling the package.

2. Opening the `Diagnostic.nuspec` file, you will note that this contains information regarding the NuGet package you are about to deploy. Make a point of modifying this file accordingly as it contains information important to developers consuming your NuGet package.

```
<?xml version="1.0"?>
<package xmlns="http://schemas.microsoft.com/packaging/
2011/08/nuspec.xsd">
<metadata>
  <id>PurchaseOrderAnalyzer</id>
  <version>1.1.1.1</version>
  <title>Purchase Order Analyzer</title>
  <authors>Dirk Strauss</authors>
  <owners>Acme Corporation</owners>
  <licenseUrl>http://www.acmecorporation.com/poanalyzer/
    license</licenseUrl>
  <projectUrl>http://www.acmecorporation.com/poanalyzer
    </projectUrl>
  <requireLicenseAcceptance>true</requireLicenseAcceptance>
  <description>Validate the creation of Purchase Order Objects
    within Acme Corporation's development projects
  </description>
  <releaseNotes>Initial release of the Purchase Order
    Analyzer.</releaseNotes>
  <copyright>Copyright</copyright>
  <tags>PurchaseOrderAnalyzer, analyzers</tags>
  <frameworkAssemblies>
    <frameworkAssembly assemblyName="System"
      targetFramework="" />
  </frameworkAssemblies>
</metadata>
<!-- The convention for analyzers is to put language
agnostic dlls in analyzersportable50 and language</pre>
```

```

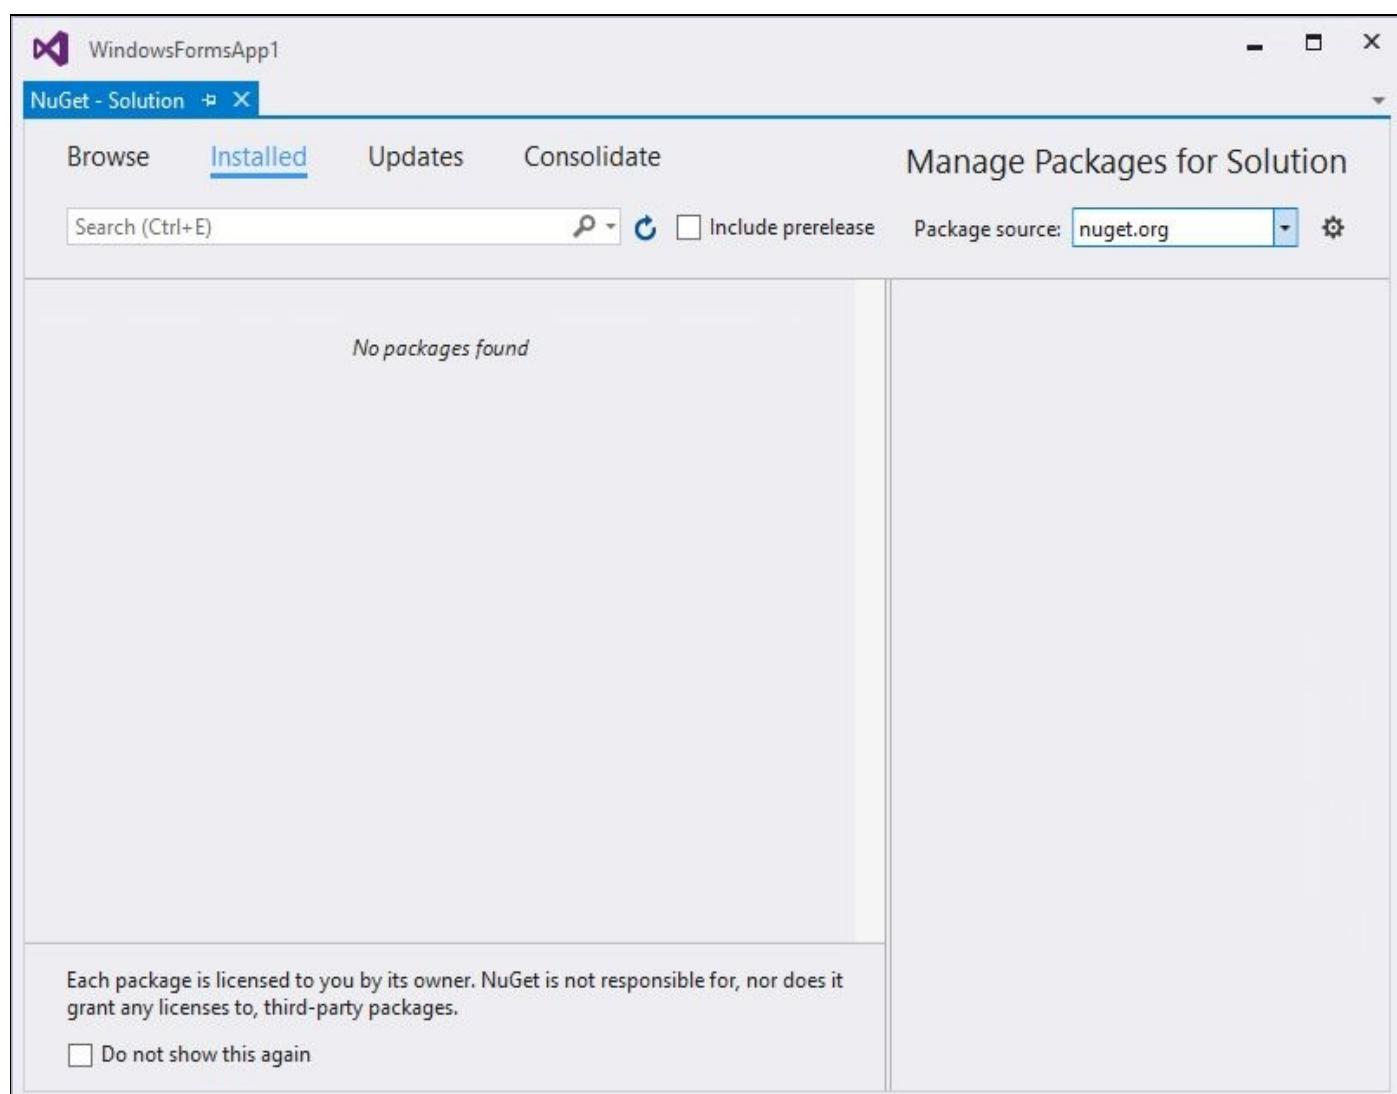

specific analyzers in either analyzersportable50cs or
analyzersportable50vb -->
<files>
  <file src="*.dll" target="analyzersdotnetcs"
    exclude="**Microsoft.CodeAnalysis.*;
    **System.Collections.Immutable.*;
    **System.Reflection.Metadata.*;
    **System.Composition.*" />
  <file src="tools*.ps1" target="tools" />
</files>
</package>

```

3. Go ahead and build your code analyzer. You will see that a file called `PurchaseOrderAnalyzer.1.1.1.1.nupkg` has been created in the `bin` folder for your project. Copy that file to the mapped drive you created earlier in the Azure Storage account.
4. Inside Visual Studio, add a new WinForms application. You can call this anything you like. You can now add the Storage account as a NuGet location. Go to Tools, NuGet Package Manager and click on Manage NuGet Packages for Solution.... You will notice that, next to the Package source, which is currently set to `nuget.org`, there is a small gear icon. Click on this.

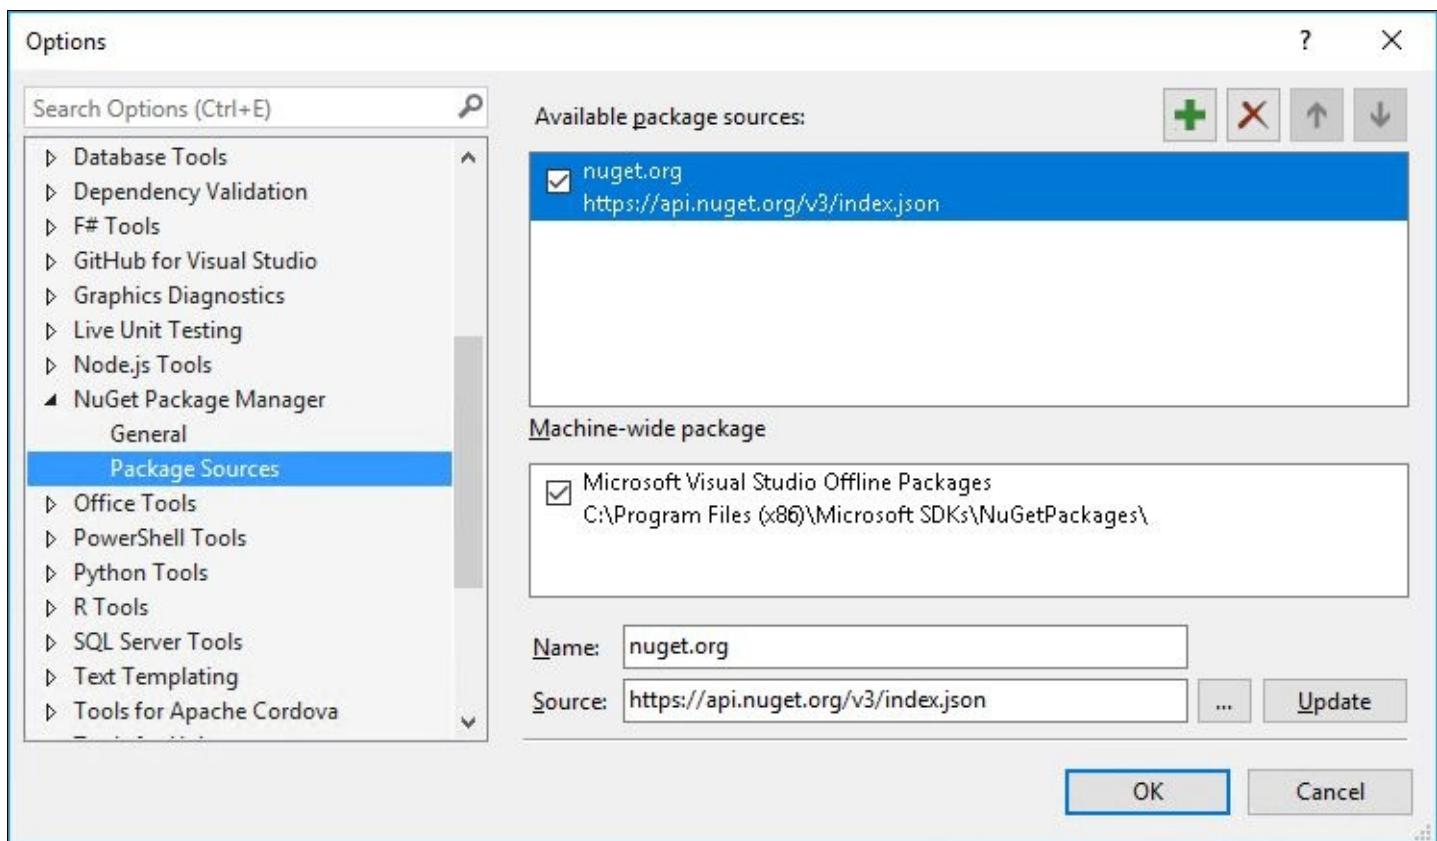

*I created the Visual Studio WinForms application on a separate machine for this example, but if you do not have access to a separate machine, try using a VM to test this. If you do not have access to Azure, you can use VirtualBox.*

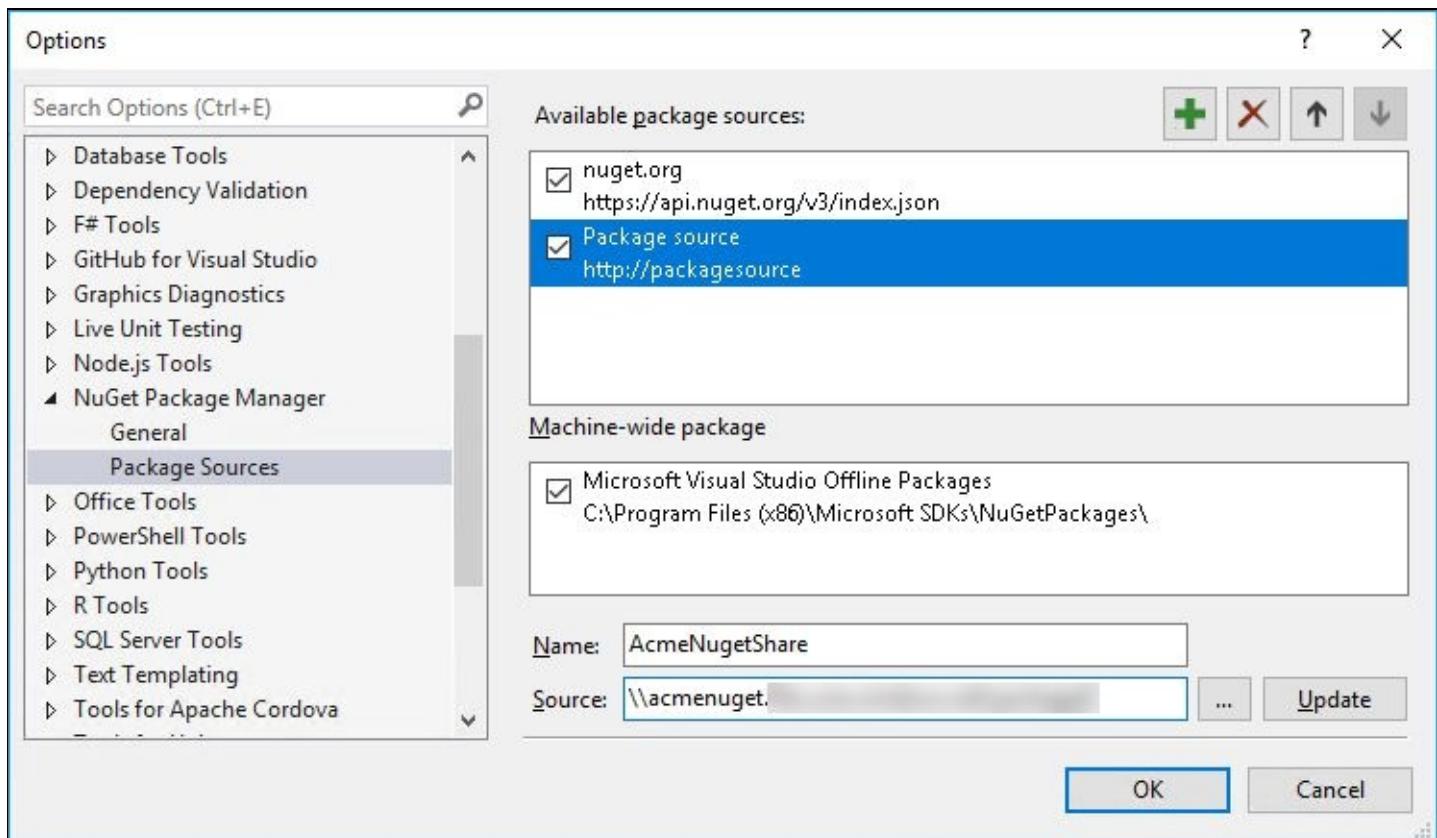

5. The Options screen allows you to add an additional source for NuGet packages by clicking on the

green plus icon under Available package sources.

- At the bottom of the Options window, enter a suitable name for the location and enter the path to the Azure Storage account. This is the same path you entered when you mapped the network drive. Before clicking on OK, click on the Update button. Then click on the OK button.

- You can now change the Package source to set it to the Azure Storage account location you mapped

to. Doing this and clicking on the Browse tab of the NuGet package manager will display all the packages on this file share. The information under the Options section to the right is the information you defined in the `Diagnostic.nuspec` file.

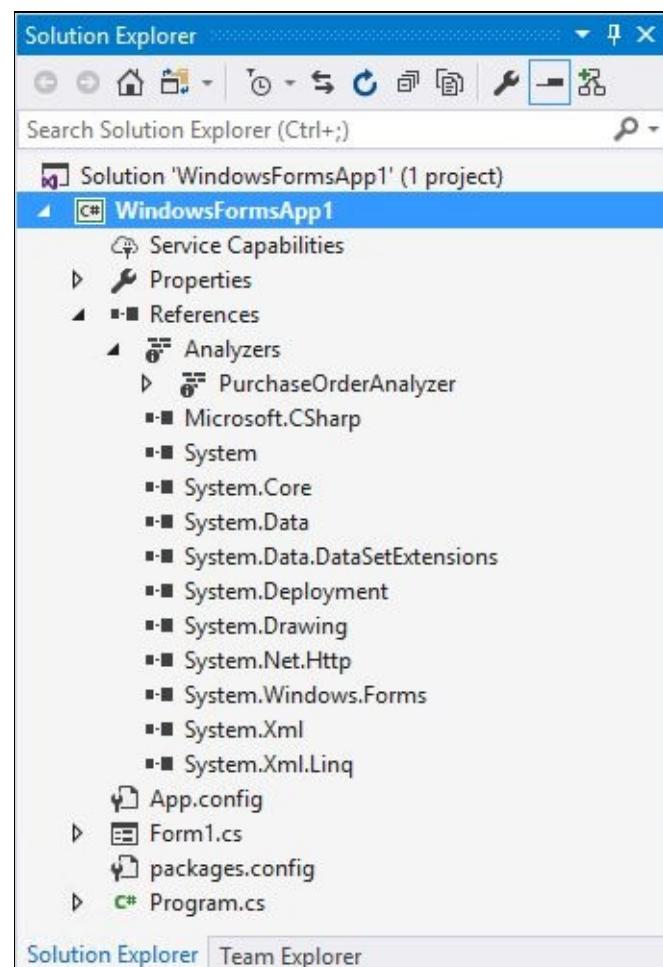

The screenshot shows the NuGet Solution Explorer interface for a project named "WindowsFormsApp1". The "Browse" tab is selected. A search bar contains "PurchaseOrderAnalyzer". The results list shows one item: "PurchaseOrderAnalyzer" by Dirk Strauss, version v1.1.1.1. The description for this package is: "Validate te creation of Purchase Order Objects withing Acme Corporation's development projects". On the right side, there is a "Manage Packages for Solution" pane titled "Options". It displays the following package details:

<b>Version:</b>	1.1.1.1
<b>Owner(s):</b>	Acme Corporation
<b>Author(s):</b>	Dirk Strauss
<b>License:</b>	<a href="http://www.acmecorporation.com/poanalyzer/license">http://www.acmecorporation.com/poanalyzer/license</a>
<b>Date published:</b>	Sunday, January 29, 2017 (1/29/2017)
<b>Project URL:</b>	<a href="http://www.acmecorporation.com/poanalyzer">http://www.acmecorporation.com/poanalyzer</a>
<b>Tags:</b>	PurchaseOrderAnalyzer, analyzers

Below the package details, the pane shows "Dependencies" and "No dependencies".

In the bottom left corner of the main window, there is a note: "Each package is licensed to you by its owner. NuGet is not responsible for, nor does it grant any licenses to, third-party packages." and a checkbox for "Do not show this again".

8. You can now go ahead and install the code analyzer NuGet package. When you have completed the installation, the code analyzer will be visible under the `Analyzers` node under `References` in your project.

9. The code analyzer also works exactly as expected. Create a class called `PurchaseOrder` and see the analyzer in action.

The screenshot shows the Visual Studio code editor with the following C# code:

```
11  namespace WindowsFormsApp1
12  {
13      public partial class Form1 : Form
14      {
15          public Form1()
16          {
17              InitializeComponent();
18          }
19
20          private void Form1_Load(object sender, EventArgs e)
21          {
22          }
23      }
24  }
25
26  public class PurchaseOrder
27  {
28  }
```

A yellow vertical bar highlights the word "PurchaseOrder" at line 26. A tooltip box appears over the word, containing the following information:

- class WindowsFormsApp1.PurchaseOrder**
- IReceiptable Interface not Implemented
- Show potential fixes (Ctrl+.)

# How it works...

The NuGet package is the easiest way to deploy code to a large audience or even a few developers. It takes all the heavy lifting out of sharing code and templates. It therefore makes perfect sense to use NuGet to deploy your code analyzers. Setting up a private repository using NuGet for sharing code within your organization is really simple.

# Regular Expressions

**Regular expressions (regex)** are something of a mystery to many developers. We admit that they are something that we use often enough to warrant a deeper understanding of how they work. On the flip side, there are so many tried and tested regex patterns on the Internet, that just reusing one that already exists is easier than trying to create one yourself most times. The subject of regex is much larger than what can be explained in a single chapter in this book.

Therefore, in this chapter, we will merely introduce some of the concepts of regex. For a deeper understanding of regex, further study is needed. For the purpose of this book, however, we will take a closer look at how regular expression are created and how they can be applied to some common programming problems. In this chapter, we will cover the following recipes:

- Getting started with regex - Matching a valid date
- Sanitize input
- Dynamic regex matching

# Introduction

A regular expression is a pattern that describes a string through the use of special characters that denote a specific bit of text to match. The use of regular expression is not a new concept in programming. For regex to work, it needs to use a regex engine that does all the heavy lifting.

In the .NET Framework, Microsoft has provided for the use of regex. To use regex, you will need to import the `System.Text.RegularExpressions` assembly to your project. This will allow the compiler to use your regex pattern and apply it to the specific text you need to match.

Secondly, regex have a specific set of metacharacters that hold special meaning to the regex engine. These characters are `[ ]`, `{ }`, `( )`, `*`, `+`, `,`, `?`, `|`, `$`, `.`, and `^`.

The use of the curly brackets `{ }`, for example, enables developers to specify the number of times a specific set of characters need to occur. Using square brackets, on the other hand, defines exactly what needs to be matched.

If we, for example, specified `[abc]`, the pattern would look for lowercase As, Bs, and Cs. regex, therefore, also allows you to define a range, for example, `[a-c]`, which is interpreted in exactly the same way as the `[abc]` pattern.

Regular expressions then also allow you to define characters to exclude using the `^` character. Therefore, typing `[^a-c]` would find lowercase D through Z because the pattern is telling the regex engine to exclude lowercase As, Bs, and Cs.

Regular expressions also define `d` and `D` a type of shortcut for `[0-9]` and `[^0-9]`, respectively. Therefore, `d` matches all numeric values, and `D` matches all non-numeric values. Another shortcut is `w` and `W`, which match any character from lowercase A to Z, irrespective of the case, all numeric values from 0 to 9, and the underscore character. Therefore, `w` is `[a-zA-Z0-9_]`, while `W` is `[^a-zA-Z0-9_]`.

The basics of regex are rather easy to understand, but there is a lot more that you can do with regex.

# Getting started with regex - Matching a valid date

If you haven't done so already, create a new console application and add a class to the project called `RegExDemo`. Your code at this moment should look something like this:

```
class Program
{
    static void Main(string[] args)
    {
    }
}

public class RegExDemo
{
}
```

# Getting ready

For the purpose of this book, we are using a console application to illustrate the use of regex. In reality, you would probably not have this logic mixed in between your production code, because this would result in code being rewritten. The best place to add something such as regex is in a helper class within an extension method.

```

using System.Text.RegularExpressions;

public void ValidDate(string stringToMatch) <br/> { <br/> <br/> }

string pattern = $@"^((19|20)dd[-./](0[1-9]|1[0-2])[-./](0[1-9]|12)[0-9]|3[01])$";

if (Regex.IsMatch(stringToMatch, pattern)) <br/> Console.WriteLine($"The string
{stringToMatch} contains a valid date."); <br/> else <br/> Console.WriteLine($"The
string {stringToMatch} DOES NOT contain a valid date.");

public void ValidDate(string stringToMatch) <br/> { <br/> string pattern =
$@"^((19|20)dd[-./](0[1-9]|1[0-2])[-./](0[1-9]|12)[0-9]|3[01])$"; <br/> <br/>
if (Regex.IsMatch(stringToMatch, pattern)) <br/> Console.WriteLine($"The string
{stringToMatch} contains<br/> a valid date."); <br/> else <br/> Console.WriteLine($"The
string {stringToMatch} DOES <br/> NOT contain a valid date."); <br/> }

RegExDemo oRecipe = new RegExDemo(); <br/> oRecipe.ValidDate("1912-12-31");
<br/> oRecipe.ValidDate("2018-01-01"); <br/> oRecipe.ValidDate("1800-01-21"); <br/>
oRecipe.ValidDate($"{DateTime.Now.Year}<br/>.{DateTime.Now.Month}.
{DateTime.Now.Day}"); <br/> oRecipe.ValidDate("2016-21-12"); <br/> Console.Read();

string pattern = $@"^((19|20)dd[-./](0[1-9]|1[0-2])[-./](0[1-9])|12)[0-9]|3[01])$";

```

11. Run the console application again and look at the output:

```

The string 1912-12-31 contains a valid date.
The string 2018-01-01 contains a valid date.
The string 1800-01-21 DOES NOT contain a valid date.
The string 2016.4.10 contains a valid date.
The string 2016-21-12 DOES NOT contain a valid date.

```

This time the regex worked for all the given date strings. But what exactly did we do? This is how it works.

# How it works...

Let's take a closer look at the two expressions used in the previous code example. Comparing them with each other, you can see the change we made in yellow:

```
string pattern = @"^(19|20)\d\d[-/.](0[1-9]|1[0-2])[-/.](0[1-9]|12)[0-9]|3[01])$";  
string pattern = @"^(19|20)\d\d[-/.](0[1-9]|1[0-2])|([1-9])[-/.](0[1-9]|12)[0-9]|3[01])$";
```

Before we get to what that change means, let's break up the expression and view the individual components. Our regex is basically saying that we must match all string dates that start with 19 or 20 and have the following separators:

- Dash (-)
- Decimal (.)
- Forward slash (/)

To understand the expression better, we need to understand the following format of the expression <Valid Years><Valid Separators><Valid Months><Valid Separators><Valid Days>.

We also need to be able to tell the regex engine to consider one *OR* another pattern. The word *OR* is symbolized by the | metacharacter. To make the regex engine consider the word *OR* without splitting up the whole expression, we wrap it in the parenthesis () .

Here are the symbols used in the regex:

The conditional OR	Description
	This denotes the <i>OR</i> metacharacter.
The year portion	Description
(19 20)	Only allow 19 or 20
dd	Matches two single digits between 0 and 9. To match only one digit between 0 and 9, you would use d.
The valid separator	Description

<b>character set</b>	
[ - ./]	Matches any of the following characters in the character set. These are our valid separators. To match a space date separator, you would change this to [- ./], where you add a space anywhere in the character set. We added the space between the dash and the decimal.
<b>Valid digits for months and days</b>	<b>Description</b>
0[1-9]	Matches any part starting with zero followed by any digit between 1 and 9. This will match 01, 02, 03, 04, 05, 06, 07, 08, and 09.
1[0-2]	Matches any part starting with 1 followed by any digit between 0 and 2. This will match 10, 11, or 12.
[1-9]	Matches any digit between 1 and 9.
[12][0-9]	Matches any part starting with 1 or 2 followed by any digit between 0 and 9. This will match all number strings between 10 and 29.
3[01]	Matches any part starting with 3 and followed by 0 or 1. This will match 30 or 31.
<b>Start and end of string</b>	<b>Description</b>
^	Tells the regex engine to start at the beginning of the given string to match.
\$	Tells the regex engine to stop at the end of the given string to match.

The first regex we created, interprets as follows:

- `^`: Start at the beginning of the string to match
- `(19|20)`: Check whether the string starts with 19 or 20
- `dd`: After the check, follows two single digits between 0 and 9
- `[-./]`: The year portion ends followed by a date separators
- `(0[1-9]|1[0-2])`: Find the month logic by looking for digits starting with 0, followed by any digit between 1 and 9, OR digits starting with 1, followed by any digit between 0 and 2
- `[-./]`: The month logic ends followed by a date separator
- `(0[1-9]|12)[0-9]|3[01])`: Then, find the day logic by looking for digits starting with 0, followed by a digit between 1 and 9, OR digits starting with 1 or 2, followed by any digit between 0 and 9, OR a digit matching 3, followed by any digit between 0 and 1
- `$`: Do this until the end of the string

Our first regex was incorrect because our month logic was incorrect. Our month logic dictates to find the month logic by looking for digits starting with a 0 followed by any digit between 1 and 9 or digits starting with a 1 followed by any digit between 0 and 2 (`0[1-9]|1[0-2]`).

This will then find 01, 02, 03, 04, 05, 06, 07, 08, 09, or 10, 11, 12. The date that it didn't match was `2016.4.10` (the date separators don't make a difference here). This is because our month came through as a single digit, and we were looking for months where the single digits started with a zero. To fix this, we had to modify the expression of the month logic to include single digits only between 1 and 9. We did this by adding `[1-9]` to the expression at the end.

The modified regex then read as follows:

- `^`: Start at the beginning of the string to match
- `(19|20)`: Check whether the string starts with 19 or 20
- `dd`: After the check, follows two single digits between 0 and 9
- `[-./]`: The year portion ends followed by a date separator
- `(0[1-9]|1[0-2])`: Find the month logic by looking for digits starting with 0, followed by any digit between 1 and 9, OR digits starting with 1, followed by any digit between 0 and 2 or any single digits between 1 and 9
- `[-./]`: The month logic ends followed by a date separator
- `(0[1-9]|12)[0-9]|3[01])`: Then, find the day logic by looking for digits starting with 0, followed by a digit between 1 and 9, OR digits starting with 1 or 2, followed by any digit between 0 and 9, OR a digit matching 3, followed by any digit between 0 and 1
- `$`: Do this until the end of the string

This is a basic regex, and we say basic because there is a lot more we can do to make the expression better. We can include logic to consider alternative date formats such as `mm-dd-yyyy` or `dd-mm-yyyy`. We can add logic to check February and validate that it contains only 28 days, unless it is a leap year, in which case we need to allow the twenty-ninth day of February. Furthermore, we can also extend the regex to check that January, March, May, July, August, October, and December have 31 days while April, June, September, and November contain only 30 days.

# Sanitizing input

Sometimes, you will need to sanitize input. This could be to prevent SQL injections or ensure that an entered URL is valid. In this recipe, we will look at replacing the bad words in a string with asterisks. We are sure that there are more elegant and code-efficient methods of writing sanitation logic using regex (especially when we have a large collection of blacklist words), but we want to illustrate a concept here.

# Getting ready

Ensure that you have added the correct assembly to your class. At the top of your code file, add the following line of code if you haven't done so already:

```
| using System.Text.RegularExpressions;
```

```
public string SanitizeInput(string input) <br/> { <br/> <br/> }

List<string> lstBad = new List<string>(new string[]<br/> { "BadWord1", "BadWord2",
"BadWord3" });

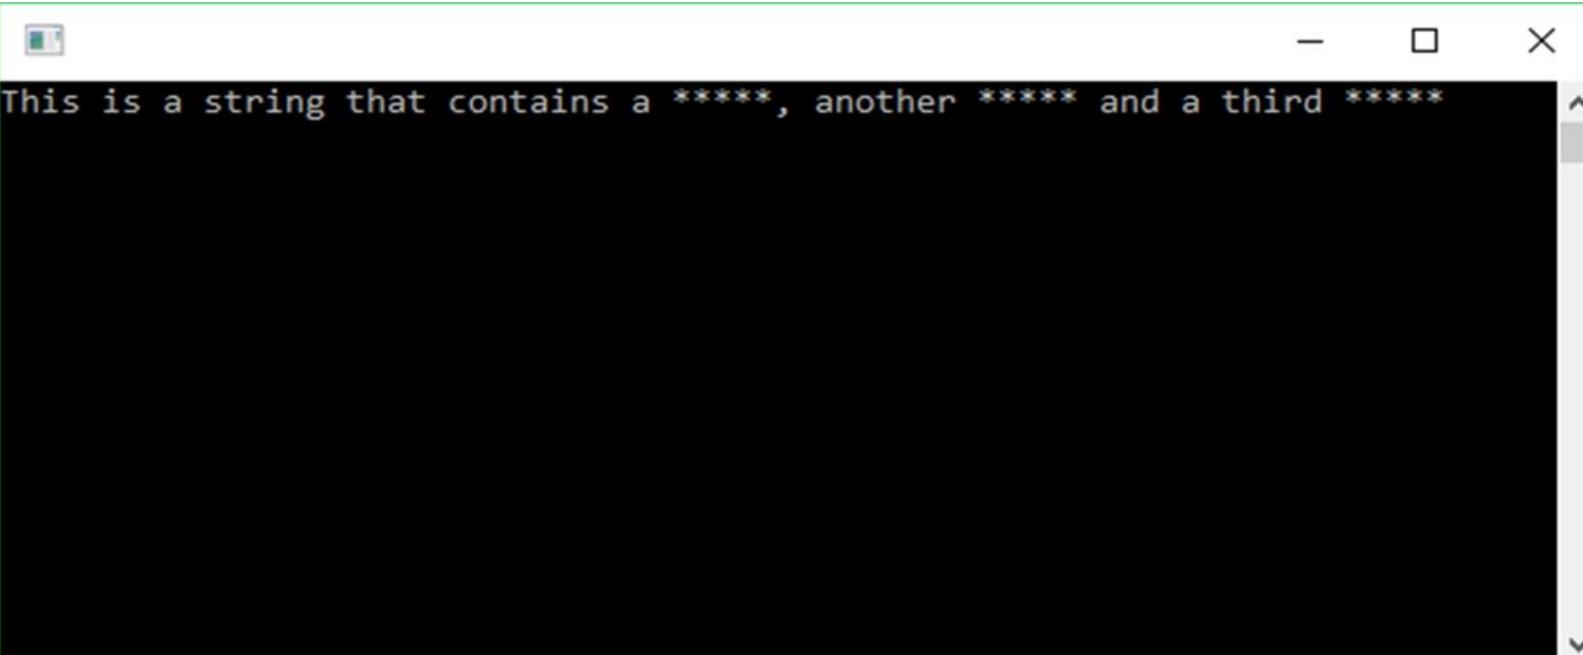

string pattern = ""; <br/> foreach (string badWord in lstBad) <br/> pattern += pattern.Length == 0 ? $"{{badWord}}" <br/> : $"|{{badWord}}"; <br/> <br/> pattern =
$@@"b({pattern})b";

return Regex.Replace(input, pattern, "*****", <br/> RegexOptions.IgnoreCase);

public string SanitizeInput(string input) <br/> { <br/> List<string> lstBad = new
List<string>(new string[]<br/> { "BadWord1", "BadWord2", "BadWord3" }); <br/> string
pattern = ""; <br/> foreach (string badWord in lstBad) <br/> pattern += pattern.Length ==
0 ? $"{{badWord}}" : $"|{{badWord}}"; <br/> <br/> pattern = $@@"b({pattern})b"; <br/>
<br/> return Regex.Replace(input, pattern, "*****", <br/> RegexOptions.IgnoreCase);
<br/> }

string textToSanitize = "This is a string that contains a <br/> badword1, another
Badword2 and a third badWord3"; <br/> RegExDemo oRecipe = new RegExDemo();
<br/> textToSanitize = oRecipe.SanitizeInput(textToSanitize); <br/>
WriteLine(textToSanitize); <br/> Read();
```

7. When you run your application, you will see the following in the console window:

The screenshot shows a Windows Command Prompt window with a black background and white text. The title bar is partially visible at the top. The main content area displays the following text:  
This is a string that contains a \*\*\*\*\*, another \*\*\*\*\* and a third \*\*\*\*\*

Let's take a closer look at the regular expression generated.

# How it works...

Let's step through the code to understand what is happening. We need to get a regex that looks like this:

b(wordToMatch1|wordToMatch2|wordToMatch3)b.

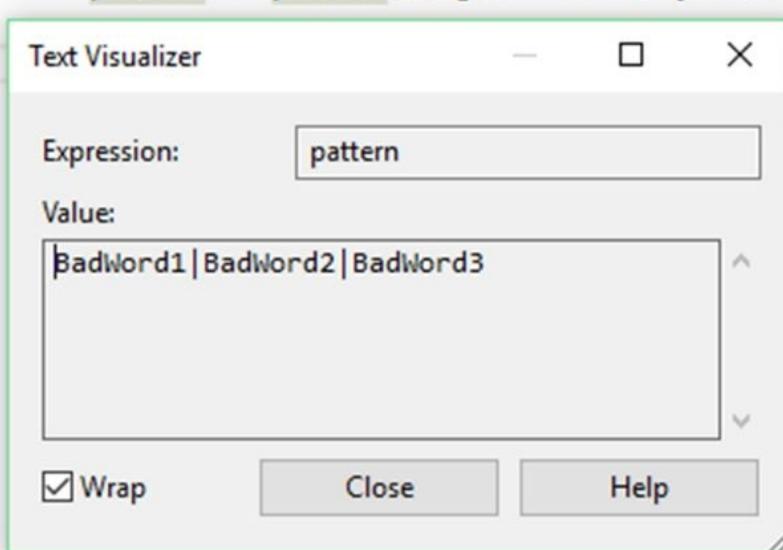

What this basically says is "find me any of the words and only whole words which are denoted by b".

When we look at the list we created, we will see the words we want to remove from the input string:

```
1 reference
public string SanitizeInput(string input)
{
    List<string> lstBad = new List<string>(new string[] { "BadWord1", "BadWord2", "BadWord3" });
    string pattern = "";
    foreach (string b in lstBad)
        pattern += $"|{b}";
    pattern = $"@\\b({pattern})";
    return Regex.Replace(input, pattern, "*****", RegexOptions.IgnoreCase);
}
```

We then created a simple loop that will create the list of words to match using the OR metacharacter. We ended up with a BadWord1|BadWord2|BadWord3 pattern after the foreach loop has completed. However, this is still not a valid regex:

```
1 reference
public string SanitizeInput(string input)
{
    List<string> lstBad = new List<string>(new string[] { "BadWord1", "BadWord2", "BadWord3" });
    string pattern = "";
    foreach (string badWord in lstBad)
        pattern += pattern.Length == 0 ? $"{{badWord}}" : $"|{{badWord}}";
}
```

The screenshot shows the Visual Studio Text Visualizer window. The expression is set to 'pattern'. The value is displayed as 'BadWord1|BadWord2|BadWord3'. There is a checkbox for 'Wrap' and buttons for 'Close' and 'Help'.

To complete the pattern resulting in the valid regex, we need to add the b expression on either side of the pattern to tell the regex engine to only match whole words. As you can see, we are using string interpolation.

It is here, however, that we need to be very careful. Start off by writing the code to complete the pattern

without the @ sign as follows: pattern = \$"b({pattern})b";

If you run your console application, you will see that the bad words are not matched and filtered out. This is because we have not escaped the character before b. The compiler, therefore, interprets this line of code:

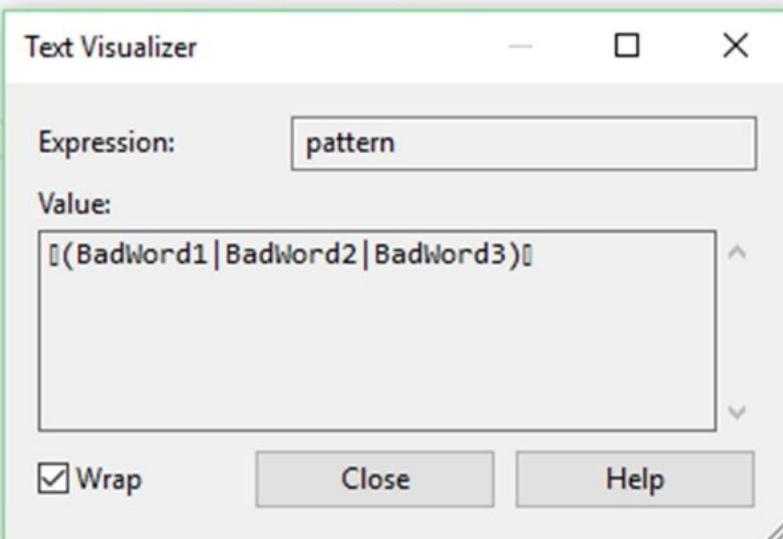

```
1 reference
public string SanitizeInput(string input)
{
    List<string> lstBad = new List<string>(new string[] { "BadWord1", "BadWord2", "BadWord3" });
    string pattern = "";
    foreach (string badWord in lstBad)
        pattern += pattern.Length == 0 ? $"{badWord}" : $"|{badWord}";

    pattern = $"\\b({pattern})\\b";
}

Text Visualizer
Expression: pattern
Value: [(BadWord1|BadWord2|BadWord3)]
egexOptions.IgnoreCase);

}

```

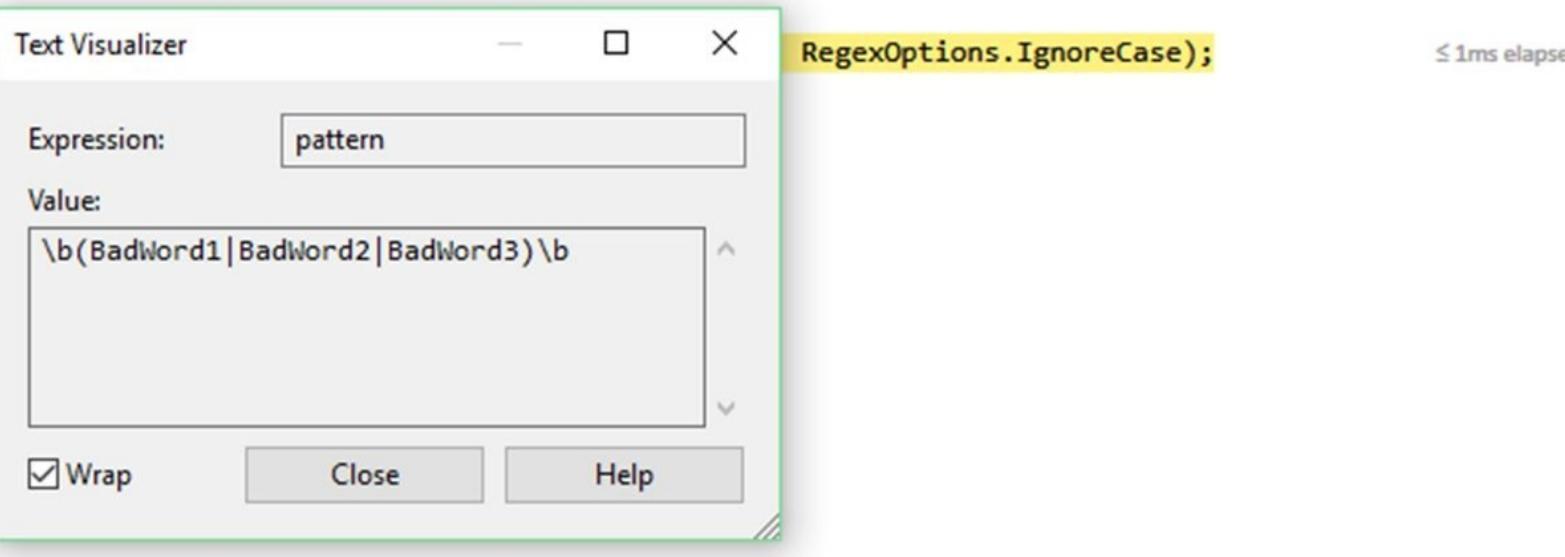

The generated expression [(BadWord1|BadWord2|BadWord3)] is not a valid expression and will, therefore, not sanitize the input string.

To correct this, we need to add the @ symbol before the string to tell the compiler to treat the string as a literal. This means any escape sequences are ignored. The correctly formatted line of code looks like this: pattern = \$"@b({pattern})b";

Once you do this, the string for the pattern is interpreted literally by the compiler, and the correct regex pattern generated:

```
1 reference
public string SanitizeInput(string input)
{
    List<string> lstBad = new List<string>(new string[] { "BadWord1", "BadWord2", "BadWord3" });
    string pattern = "";
    foreach (string badWord in lstBad)
        pattern += pattern.Length == 0 ? ${badWord}" : $"|{badWord}";

    pattern = ${@"\b({pattern})\b"};
}
```

With our correct regex pattern, we called the `Regex.Replace()` method. It takes the input to check, the regex to match, the text to replace the matched words with, and optionally allows for the ignoring of the case:

```

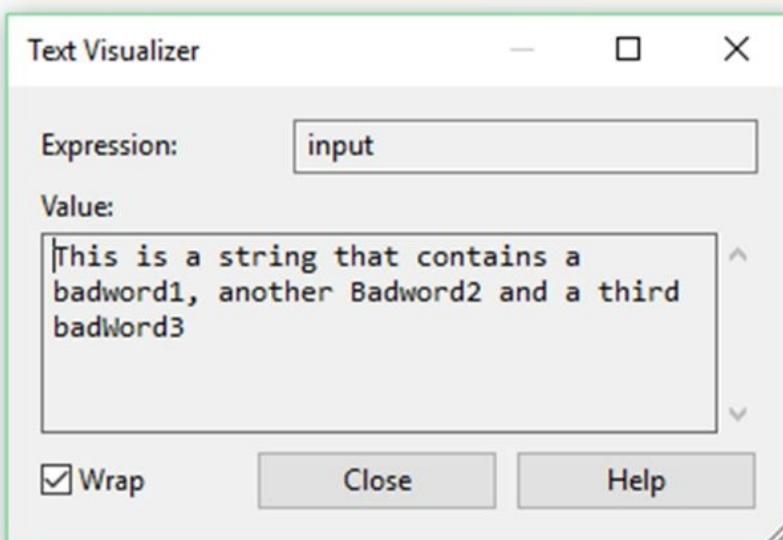

1 reference
public string SanitizeInput(string input)
{
    List<string> lstBad = new List<string>(new string[] { "BadWord1", "BadWord2", "BadWord3" });
    string pattern = "";
    foreach (string badWord in lstBad)
        pattern += pattern.Length == 0 ? $"{badWord}" : $"|{badWord}";

    pattern = $"@\"\\b({pattern})\\b\";

    return Regex.Replace(input, pattern, "*****", RegexOptions.IgnoreCase);
}

```

≤ 1ms elapsed

When the string returns to the calling code in the console application, the string will be sanitized properly:

Regex can become quite complex and can be used to perform a multitude of tasks to format and validate input and other text.

# Dynamic regex matching

What does dynamic regex matching even mean? Well, it isn't an official term, but it is a term we use to explain a regex that uses variables at runtime to generate a specific expression. Assume for a minute that you are working on a document-management system that needs to implement versioning of documents for a company called ACME Corporation. To do this, the system validates that the document has a valid filename.

A business rule states that the filename of any file uploaded on a specific day must be prefixed with acm (for ACME) and today's date in the yyyy-mm-dd format. They can be only text files, Word documents (only .docx) and Excel documents (only .xlsx). Any documents not conforming to this file format are processed by another method that takes care of archive and invalid documents.

The only task that your method needs to perform is to process fresh documents as version one documents.

*In a production system, further logic will probably be needed to determine whether the same document has been uploaded previously on the same day. This, however, is beyond the scope of this chapter. We are just trying to set the scene.*

# Getting ready

Ensure that you have added the correct assembly to your class. At the top of your code file, add the following line of code if you haven't already done so:

```
| using System.Text.RegularExpressions;
```

```
public static class CustomRegexHelper <br/> { <br/> <br/> <br/> }

public static bool ValidAcmeCompanyFilename(this string value) <br/> { <br/> <br/> }

return Regex.IsMatch(value, @"^acm[_]{DateTime.Now.Year}[_]<br/>
({_DateTime.Now.Month}|0{_DateTime.Now.Month})[_]<br/>
({_DateTime.Now.Day}|0{_DateTime.Now.Day})(.txt|.docx|.xlsx)$");

public static class CustomRegexHelper <br/> { <br/> public static bool
ValidAcmeCompanyFilename(this String value) <br/> { <br/> return
Regex.IsMatch(value, @"^acm[_]{DateTime.Now.Year}[_]<br/>
({_DateTime.Now.Month}|0{_DateTime.Now.Month})[_]<br/>
({_DateTime.Now.Day}|0{_DateTime.Now.Day})(.txt|.docx|.xlsx)$"); <br/> } <br/> }

public static void DemoExtensionMethod() <br/> { <br/> <br/> }

Console.WriteLine($"Today's date is: {_DateTime.Now.Year}-{_DateTime.Now.Month}-{_DateTime.Now.Day}");<br/>
Console.WriteLine($"The file must match: acm_{_DateTime.Now.Year}<br/>
{_DateTime.Now.Month}_{_DateTime.Now.Day}.txt including <br/> leading month and
day zeros");<br/> Console.WriteLine($"The file must match: acm_{_DateTime.Now.Year}<br/>
{_DateTime.Now.Month}_{_DateTime.Now.Day}.docx including <br/> leading
month and day zeros");<br/> Console.WriteLine($"The file must match:
acm_{_DateTime.Now.Year}<br/> {_DateTime.Now.Month}_{_DateTime.Now.Day}.xlsx
including <br/> leading month and day zeros");

string filename = "acm_2016_04_10.txt"; <br/> if
(filename.ValidAcmeCompanyFilename()) <br/> Console.WriteLine($"{filename} is a
valid file name"); <br/> else <br/> Console.WriteLine($"{filename} is not a valid file
name"); <br/> <br/> filename = "acm-2016_04_10.txt"; <br/> if
(filename.ValidAcmeCompanyFilename()) <br/> Console.WriteLine($"{filename} is a
valid file name"); <br/> else <br/> Console.WriteLine($"{filename} is not a valid file
name");
```

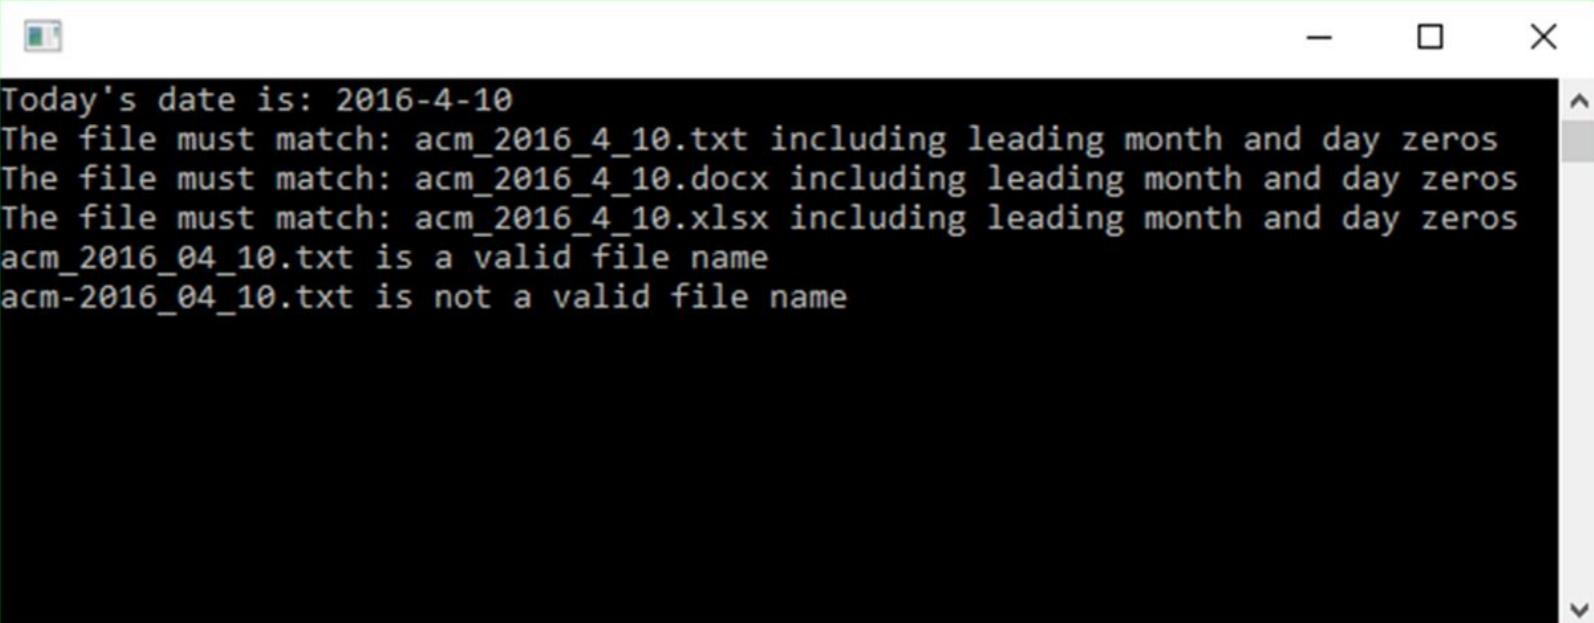

filename.ValidAcmeCompanyFilename()

```
public static void DemoExtensionMethod() <br/> { <br/> Console.WriteLine($"Today's
date is: {_DateTime.Now.Year}-{_DateTime.Now.Month}-{_DateTime.Now.Day}");<br/>
Console.WriteLine($"The file must match: acm_{_DateTime.Now.Year}<br/>
{_DateTime.Now.Month}_{_DateTime.Now.Day}.txt including leading <br/> month and
```

```
day zeros"); <br/> Console.WriteLine($"The file must match: acm_{DateTime.Now.Year}  
_ {DateTime.Now.Month}_{DateTime.Now.Day}.docx including leading month and day zeros"); <br/> Console.WriteLine($"The file must match:  
acm_{DateTime.Now.Year}<br/> _{DateTime.Now.Month}_{DateTime.Now.Day}.xlsx including leading month and day zeros"); <br/> <br/> string filename = "acm_2016_04_10.txt"; <br/> if (filename.ValidAcmeCompanyFilename()) <br/> Console.WriteLine($"{filename} is a valid file name"); <br/> else <br/> Console.WriteLine($"{filename} is not a valid file name"); <br/> filename = "acm-2016_04_10.txt"; <br/> if (filename.ValidAcmeCompanyFilename()) <br/> Console.WriteLine($"{filename} is a valid file name"); <br/> else <br/> Console.WriteLine($"{filename} is not a valid file name"); <br/> }
```

DemoExtensionMethod();

11. When you are done, run your console application:

The screenshot shows a Windows Command Prompt window with a black background and white text. The window title bar is visible at the top. The text output from the application is as follows:

```
Today's date is: 2016-4-10  
The file must match: acm_2016_4_10.txt including leading month and day zeros  
The file must match: acm_2016_4_10.docx including leading month and day zeros  
The file must match: acm_2016_4_10.xlsx including leading month and day zeros  
acm_2016_04_10.txt is a valid file name  
acm-2016_04_10.txt is not a valid file name
```

```
return Regex.IsMatch(value, $@"^acm[_]{DateTime.Now.Year}[_]
({_DateTime.Now.Month}|0{_DateTime.Now.Month})[_]
({_DateTime.Now.Day}|0{_DateTime.Now.Day})](_.txt|.docx|.xlsx)$");
```

To appreciate what is happening, we need to break this expression up into the different components:

### The conditional OR

|

### Description

This denotes the *OR* metacharacter.

### The file prefix and separator

acm

### Description

The file must begin with the text acm.

[\_]

The only valid separator between the date components and the prefix in the file name is an underscore.

### The date parts

{DateTime.Now.Year}

The interpolated year part of the date for the file name.

{DateTime.Now.Month}

The interpolated month part of the date for the file name.

0[{DateTime.Now.Month}]

The interpolated month part of the date with a leading zero for the file name.

{DateTime.Now.Day}

The interpolated day part of the date for the file name.

0[{DateTime.Now.Day}]

The interpolated day part of the date with a leading zero for the file name.

### Valid file formats

(.txt|.docx|.xlsx)

Match any of these file extensions for text documents, Word documents, or Excel documents.

### Start and end of string

^

Description

Tells the regex engine to start at the beginning of the given string to match

\$

Tells the regex engine to stop at the end of the given string to match

Creating the regex in this manner allows us to always have it stay up to date. As we have to always match the current date to the file being validated, this creates a unique challenge that is easily overcome using string interpolation, `DateTime`, and regex *OR* statements.

Having a look at some of the more useful bits of regex, you will see that this chapter has not even begun to scratch the surface of what can be accomplished. There is a whole lot more to explore and learn. There are many resources on the Internet as well as some free (some online) and commercial tools that will assist you in creating regex.

# Working with Files, Streams, and Serialization

Working with files, streams, and serialization is something you as a developer will do many times. Creating import files, exporting data to a file, persisting an application state, using a file definition to build a file, and many other scenarios will present themselves at some point during your career. In this chapter, we will look at the following:

- Creating and extracting ZIP archives
- In-memory stream compression and decompression
- Async and await file processing
- How to make a custom type serializable
- Using `ISerializable` for custom serialization to a `FileStream`
- Using `XmlSerializer`
- JSON serializers

# Introduction

Being able to work with files will definitely give you an edge as a developer. There are so many frameworks for working with files available to developers today, that one tends to forget that some of the functionality you want is already rolled up into the .NET Framework itself. Let's look at what exactly we can do with files.

*If you ever find that you need to create Excel files in ASP.NET applications, do have a look at the excellent EPPlus .NET library available on CodePlex. At the time of writing, the URL was: <https://epplus.codeplex.com/> and is licensed under the **GNU Library General Public License (LGPL)**. Also consider donating to EPPlus. These folks wrote an incredible library that is very easy to use and well documented.*

*On March 31, 2017 it was announced that CodePlex would be shut down completely on December 15, 2017. According to the DISCUSSIONS tab on the EPPlus CodePlex page (<https://epplus.codeplex.com/discussions/662424>) the source code will be moved to GitHub before CodePlex goes into read-only mode in October 2017.*

# Creating and extracting ZIP archives

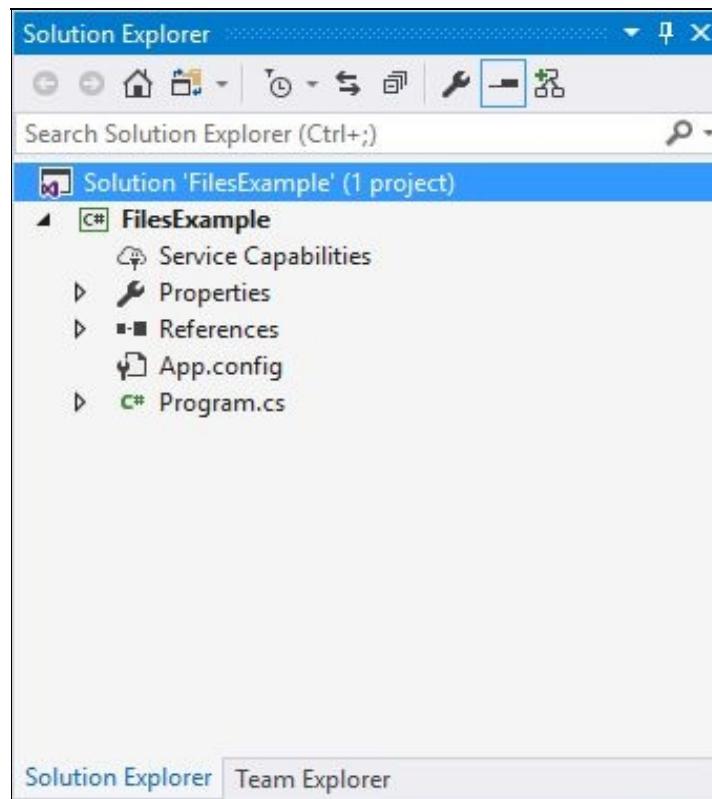

One of the most basic things you can do is work with ZIP files. The .NET Framework does an excellent job at providing this functionality right out of the box. You might need to provide ZIP functionality in an application that needs to upload several files to a network share. Being able to ZIP several files and upload a single ZIP file makes more sense than having to upload several smaller files.

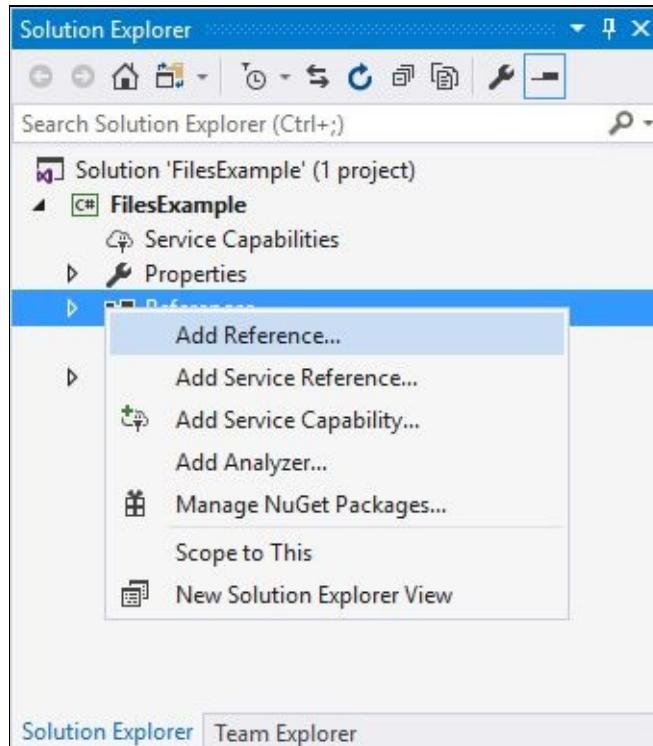

# Getting ready

Perform the following steps:

1. Create a console application and call it `FilesExample`:

2. Right-click on the References node and select Add Reference... from the context menu:

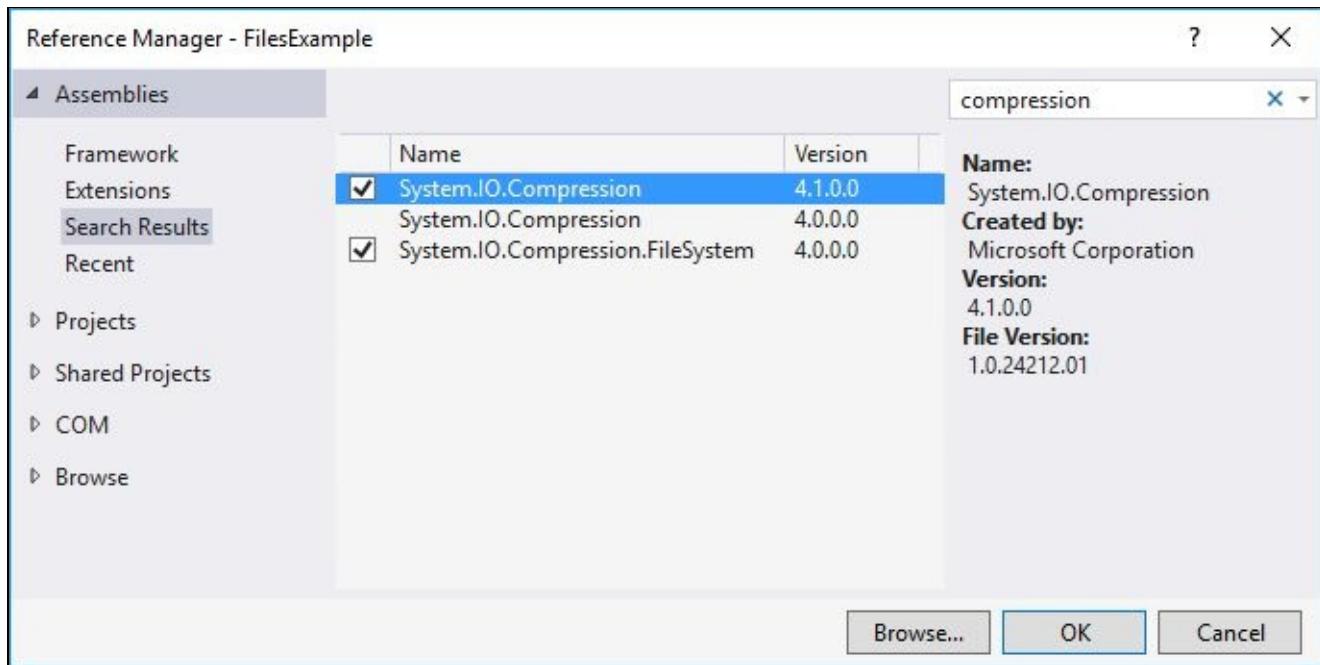

3. In the Reference Manager, search for the word `compression`. Add a reference to

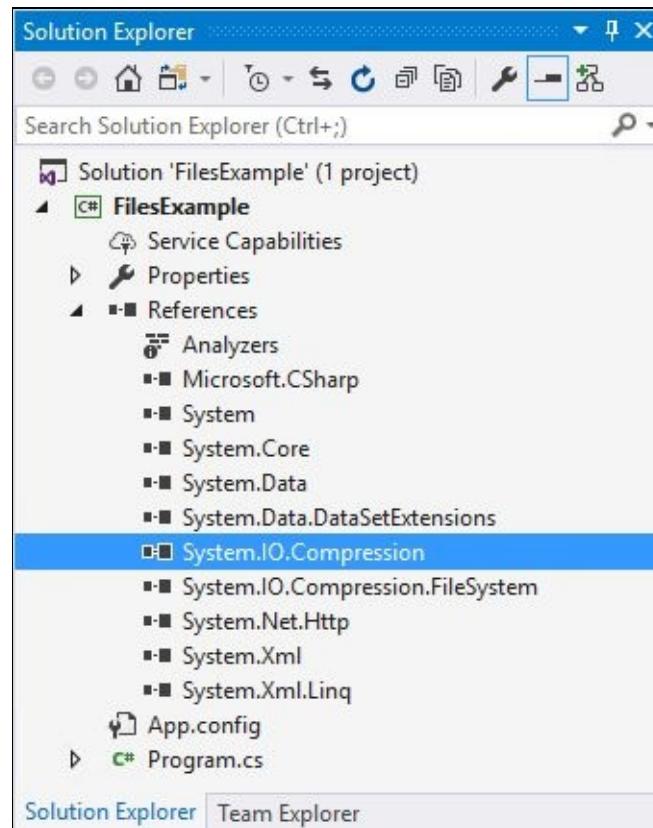

System.IO.Compression and System.IO.Compression.FileSystem to your project and click on the OK button.

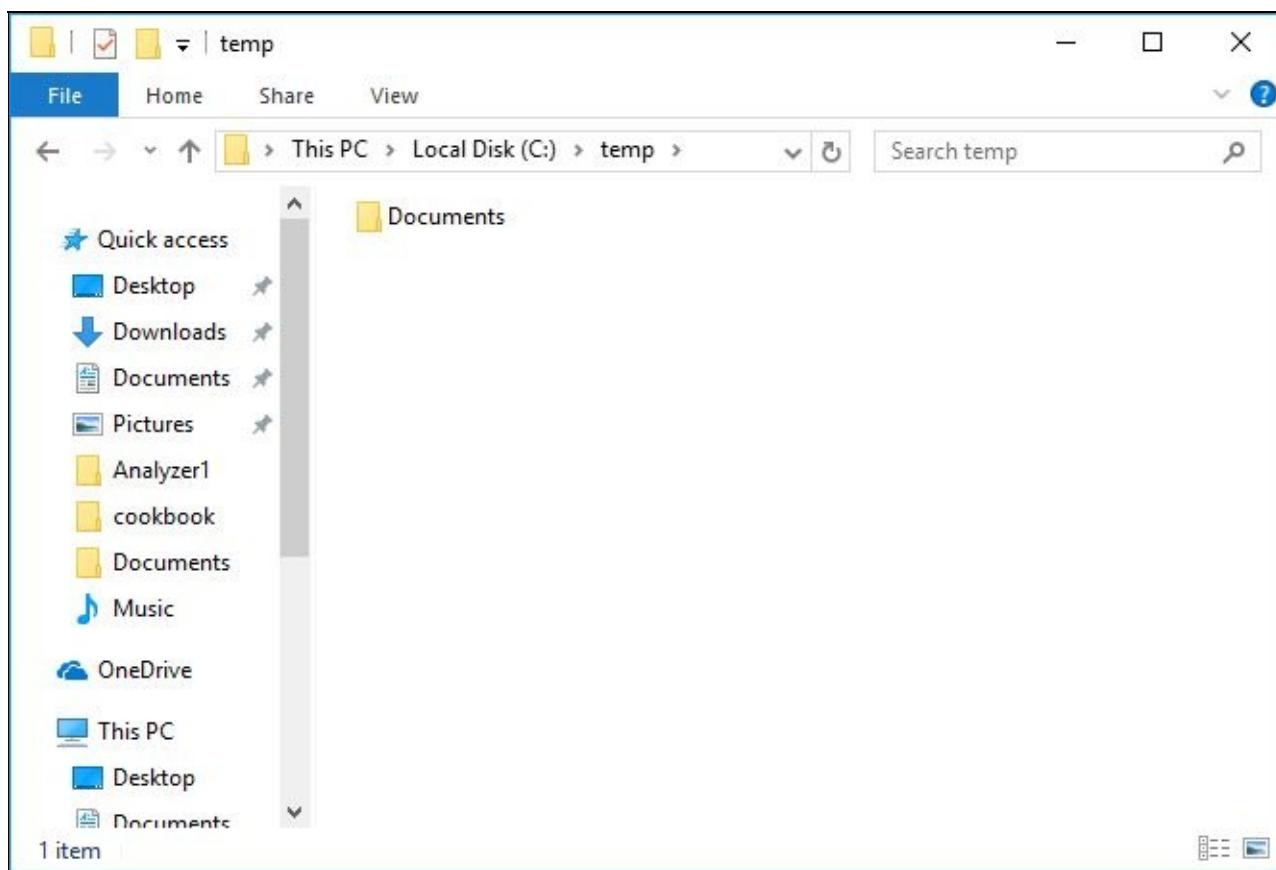

*At the time of writing, there was a System.IO.Compression version 4.1.0.0 and System.IO.Compression version 4.0.0.0 available from the Reference Manager. The example I created just used version 4.1.0.0.*

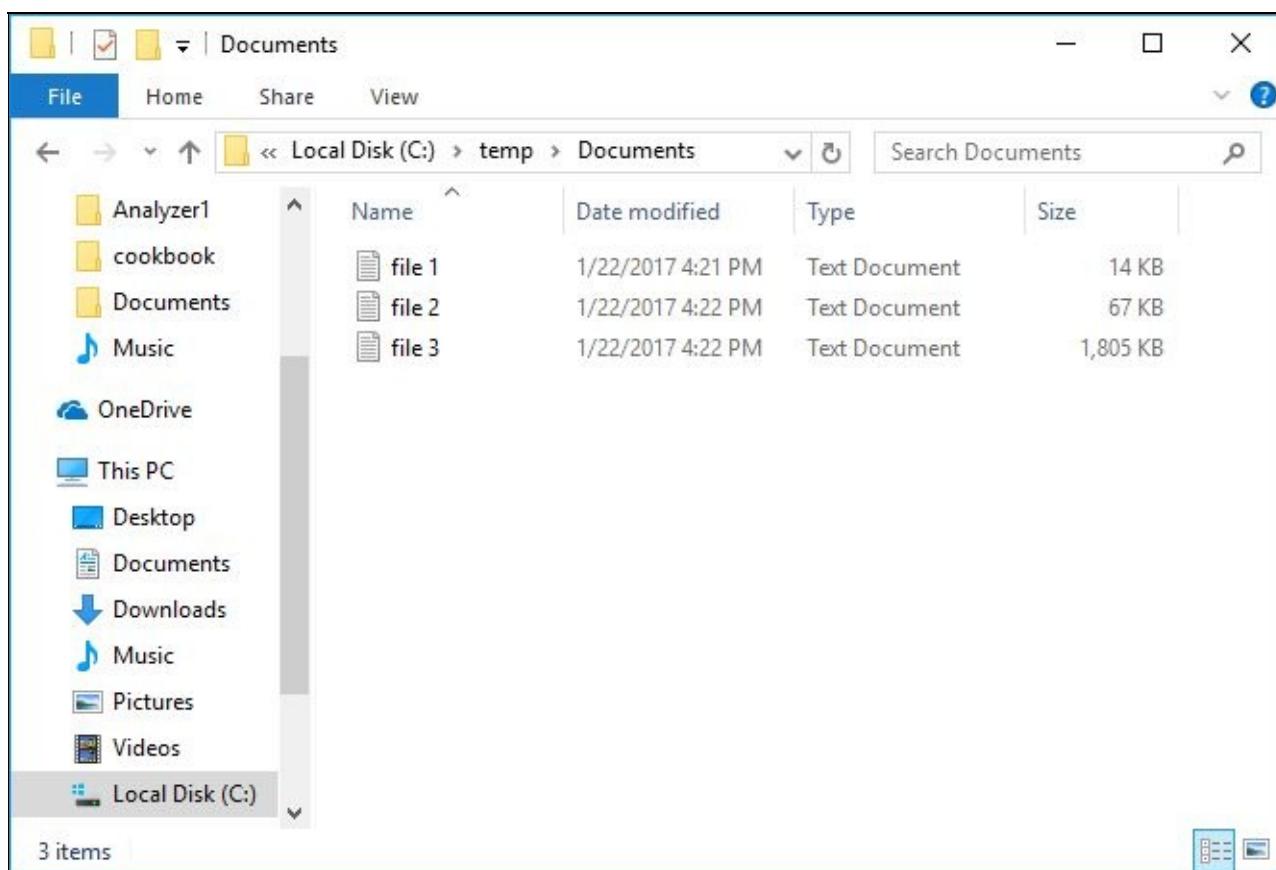

4. When you have added your references, your solution should look as follows:

5. Create a folder called `Documents` in your `temp` folder:

6. Inside this folder, create a few files of varying sizes:

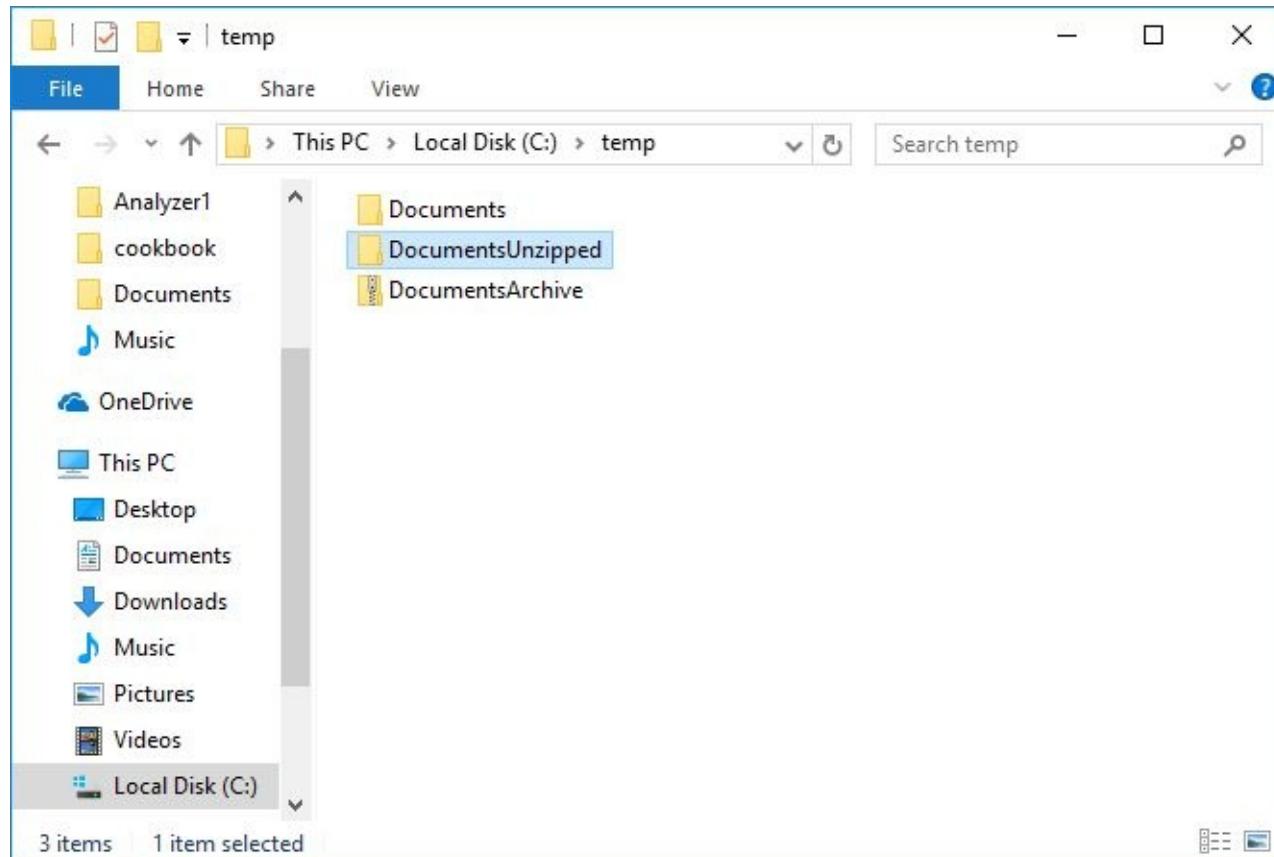

You are now ready to write some code.

```
using System.IO; using System.IO.Compression;
```

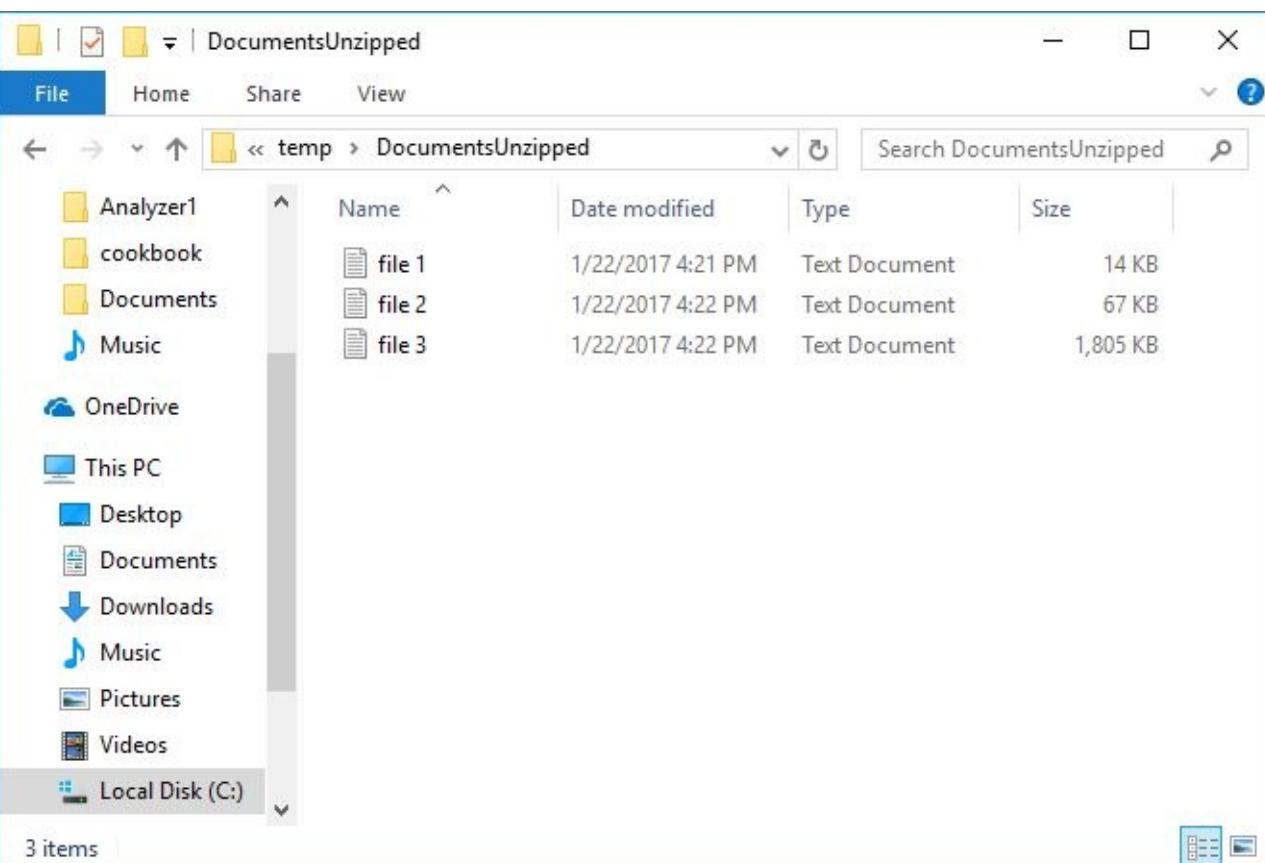

```
private static void ZipIt(string path) {  
    string sourceDirectory = $"  
    {path}Documents";  
    if (Directory.Exists(sourceDirectory)) {  
        string archiveName = $"'{path}DocumentsArchive.zip";  
        ZipFile.CreateFromDirectory(sourceDirectory, archiveName, CompressionLevel.Optimal, false);  
    }  
}
```

```
private static void UnZipIt(string path) {  
    string destinationDirectory = $"  
    {path}DocumentsUnzipped";  
    if (Directory.Exists(path)) {  
        string archiveName = $"'{path}DocumentsArchive.zip";  
        ZipFile.ExtractToDirectory(archiveName, destinationDirectory);  
    }  
}
```

7. Run your console application and view the output folder:

8. Viewing the extracted files in the DocumentsUnzipped folder, you will see the original files we started off with:

# **How it works...**

Working with ZIP files in .NET is really as easy as it gets. The .NET Framework does a lot of the heavy lifting for mundane tasks such as creating archives. It also allows developers to maintain a certain standard of code without having to "roll their own" archiving methods.

# In-memory stream compression and decompression

Sometimes, you need to perform some in-memory compression of a large amount of text. You might want to write this to a file or a database. Perhaps you need to e-mail the text as an attachment that another system will pick up and then decompress. Whatever the reason, in-memory compression and decompression is a very useful feature to have around. The best way to do this is to use extension methods. If you haven't figured this out by now, I quite like using extension methods.

```
using System.IO.Compression;<br/>using System.Text;<br/>using static System.Console;
```

```

public static class ExtensionMethods<br/> {<br/> public static byte[] CompressStream(this byte[] originalSource)<br/> {<br/><br/> }<br/><br/> public static byte[] DecompressStream(this byte[] originalSource)<br/> {<br/><br/> }<br/> }

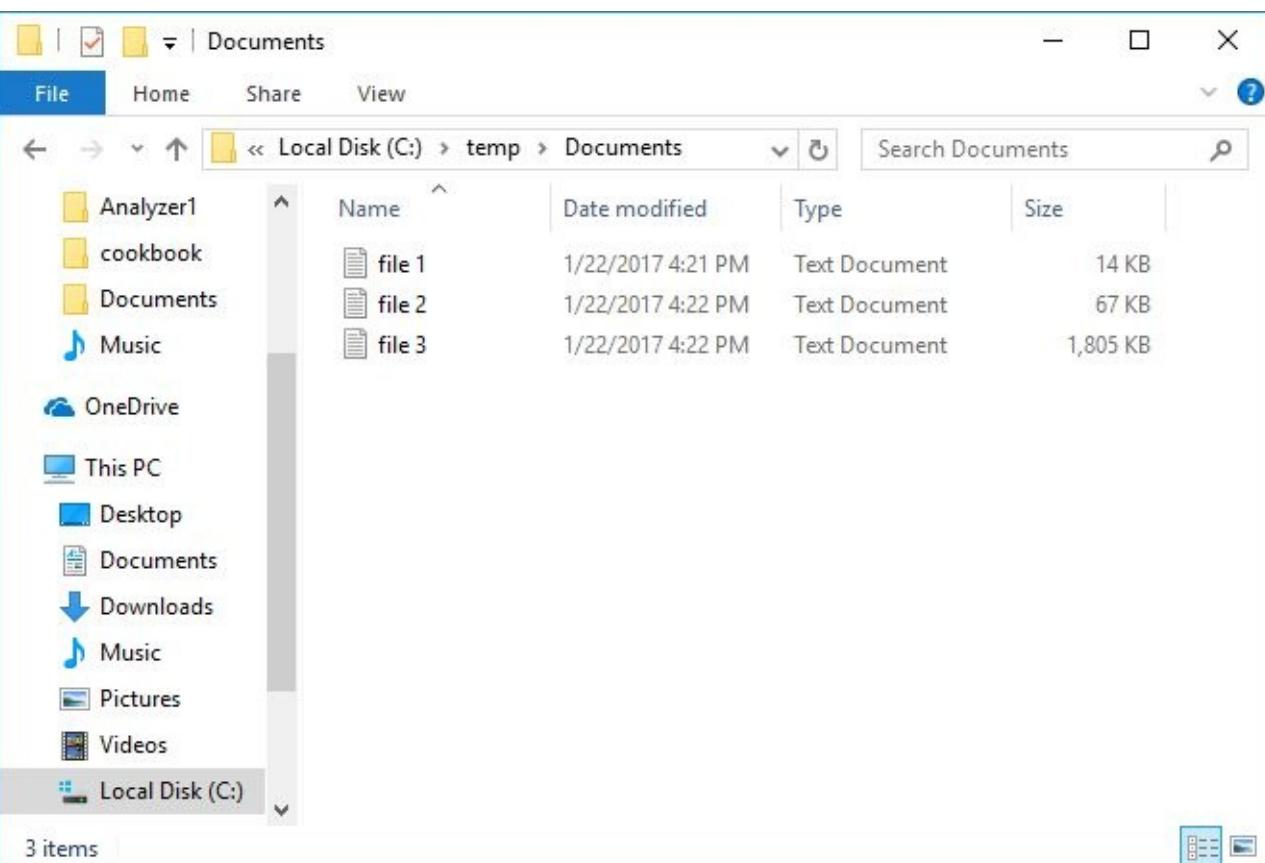

public static byte[] CompressStream(this byte[] originalSource)<br/> {<br/> using (var outStream = new MemoryStream())<br/> {<br/> using (var gzip = new GZipStream(outStream, <br/> CompressionMode.Compress))<br/> {<br/> gzip.Write(originalSource, 0, originalSource.Length);<br/> }<br/><br/> return outStream.ToArray();<br/> } <br/> }

public static byte[] DecompressStream(this byte[] originalSource)<br/> {<br/> using (var sourceStream = new MemoryStream(originalSource))<br/> {<br/> using (var outStream = new MemoryStream())<br/> {<br/> using (var gzip = new GZipStream(sourceStream, <br/> CompressionMode.Decompress))<br/> {<br/> gzip.CopyTo(outStream); <br/> }<br/> return outStream.ToArray();<br/> }<br/> }<br/> }

private static void InMemCompressDecompress()<br/> {<br/> string largeFile = @"C:\temp\Documents\file 3.txt";<br/><br/> string inputString = File.ReadAllText(largeFile);<br/> var bytes = Encoding.Default.GetBytes(inputString);<br/><br/> var originalLength = bytes.Length;<br/> var compressed = bytes.CompressStream();<br/> var compressedLength = compressed.Length;<br/><br/> var newFromCompressed = compressed.DecompressStream();<br/> var newFromCompressedLength = newFromCompressed.Length;<br/><br/> WriteLine($"Original string length = {originalLength}");<br/> WriteLine($"Compressed string length = {compressedLength}");<br/> WriteLine($"Uncompressed string length = <br/> {newFromCompressedLength}");<br/><br/> // To get the original Test back, call this<br/> //var newString = Encoding.Default.GetString(newFromCompressed);<br/> }

```

5. Ensure that you have a file called `File 3.txt` in the correct directory, as stated previously. Also, ensure that the file contains some text. You can see that the file I am going to compress in-memory is about 1.8 MB in size:

6. Running your console application will display the original length of the file, the compressed length and then the decompressed length. As would be expected, the decompressed length is the same length as the original string length:

A screenshot of a terminal window titled 'C:\sc\cookbook\working\_with\_files\FilesExample\FilesExample\...'. The window displays the following text:

```
Original string length = 1847313
Compressed string length = 27997
Uncompressed string length = 1847313
```

# How it works...

In-memory compression and decompression allows developers to use on-the-fly compression and decompression when working with objects containing large data. This can be useful for when you need to read and write log information to a database, for example. This is another example of how the .NET Framework provides developers with the perfect platform to build world-class solutions on.

# **Async and await file processing**

With `async` and `await`, developers can keep their applications fully responsive while performing intensive tasks such as file processing. This makes a perfect candidate for using asynchronous code. If you have several large files that need copying, an `async` and `await` method would be a perfect solution for keeping your form responsive.

# Getting ready

Ensure that you have added the following `using` statements to the top of your code file:

```
| using System.IO;  
| using System.Threading;
```

For asynchronous code to work, we need to include the threading namespaces.

```
CancellationTokenSource cts;<br/> int elapsedTime = 0;

public Form1(){<br/> InitializeComponent();<br/><br/> lblTimer.Text = "Timer Stopped";<br/> }

private async void btnCopyFilesAsync_Click(object sender, EventArgs e){<br/>
{<br/> if (btnCopyFilesAsync.Text.Equals("Copy Files Async")){<br/><br/> }
<br/><br/> if (btnCopyFilesAsync.Text.Equals("Cancel Async Copy")){<br/><br/>
}<br/> }

private void asyncTimer_Tick(object sender, EventArgs e){<br/> <br/> lblTimer.Text =
$"Duration = {elapsedTime += 1} seconds";<br/> }

if (btnCopyFilesAsync.Text.Equals("Cancel Async Copy")){<br/>
btnCopyFilesAsync.Text = "Copy Files Async";<br/> cts.Cancel();

if (btnCopyFilesAsync.Text.Equals("Copy Files Async")){<br/> string
sourceDirectory = @"C:\temp\AsyncSource\";<br/> string destinationDirectory =
@"C:\temp\AsyncDestination\";<br/> btnCopyFilesAsync.Text = "Cancel Async Copy";
<br/> cts = new CancellationTokenSource();<br/> elapsedTime = 0;<br/>
asyncTimer.Start();<br/><br/> IEnumerable<string> fileEntries = Directory<br/>
.EnumerateFiles(sourceDirectory);<br/> }

foreach (string sourceFile in fileEntries){<br/> using (FileStream sfs =
File.Open(sourceFile, FileMode.Open)){<br/> string destinationFilePath =
$" {destinationDirectory}{<br/> Path.GetFileName(sourceFile)}";<br/> using (FileStream
dfs = File.Create(destinationFilePath)){<br/> try{<br/> await
sfs.CopyToAsync(dfs, 81920, cts.Token);<br/> }<br/> catch
(OperationCanceledException ex){<br/> <br/> asyncTimer.Stop();<br/> lblTimer.Text =
$"Cancelled after {elapsedTime} seconds";<br/> }<br/> }<br/> }

if (!cts.IsCancellationRequested){<br/> <br/> asyncTimer.Stop();<br/> lblTimer.Text =
$"Completed in {elapsedTime} seconds";<br/> }

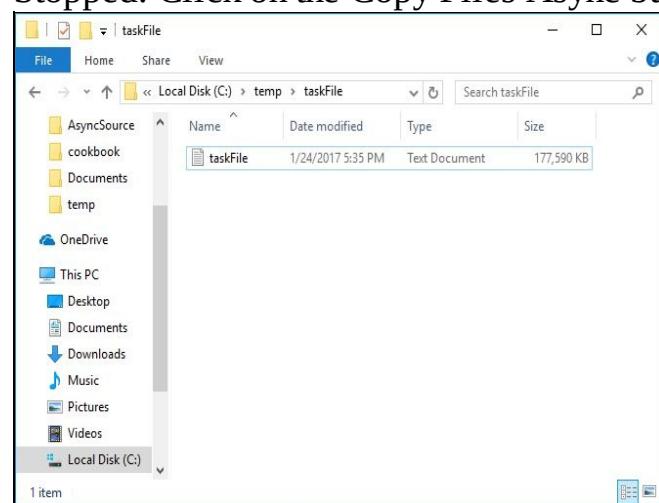

private async void btnCopyFilesAsync_Click(object sender, EventArgs e){<br/>
{<br/> if (btnCopyFilesAsync.Text.Equals("Copy Files Async")){<br/> string
sourceDirectory = @"C:\temp\AsyncSource\";<br/> string destinationDirectory =
@"C:\temp\AsyncDestination\";<br/> btnCopyFilesAsync.Text = "Cancel Async Copy";
<br/> cts = new CancellationTokenSource();<br/> elapsedTime = 0;<br/>
asyncTimer.Start();<br/><br/> IEnumerable<string> fileEntries = Directory<br/>
```

```
.EnumerateFiles(sourceDirectory);<br/><br/> //foreach (string sourceFile in  
Directory<br/> .EnumerateFiles(sourceDirectory))<br/> foreach (string sourceFile in  
fileEntries)<br/> {<br/> using (FileStream sfs = File.Open(sourceFile, FileMode.Open))  
<br/> {<br/> string destinationFilePath = $"{destinationDirectory}<br/>  
{Path.GetFileName(sourceFile)}";<br/> using (FileStream dfs =  
File.Create(destinationFilePath))<br/> {<br/> try<br/> {<br/> await  
sfs.CopyToAsync(dfs, 81920, cts.Token);<br/> }<br/> catch  
(OperationCanceledException ex)<br/> {<br/> asyncTimer.Stop();<br/> lblTimer.Text =  
$"Cancelled after {elapsedTime}<br/> seconds";<br/> }<br/> }<br/> }<br/>  
if (!cts.IsCancellationRequested)<br/> {<br/> asyncTimer.Stop();<br/> lblTimer.Text =  
$"Completed in {elapsedTime} seconds";<br/> }<br/> }<br/> if  
(btnCopyFilesAsync.Text.Equals("Cancel Async Copy"))<br/> {<br/>  
btnCopyFilesAsync.Text = "Copy Files Async";<br/> cts.Cancel();<br/> }<br/> }
```

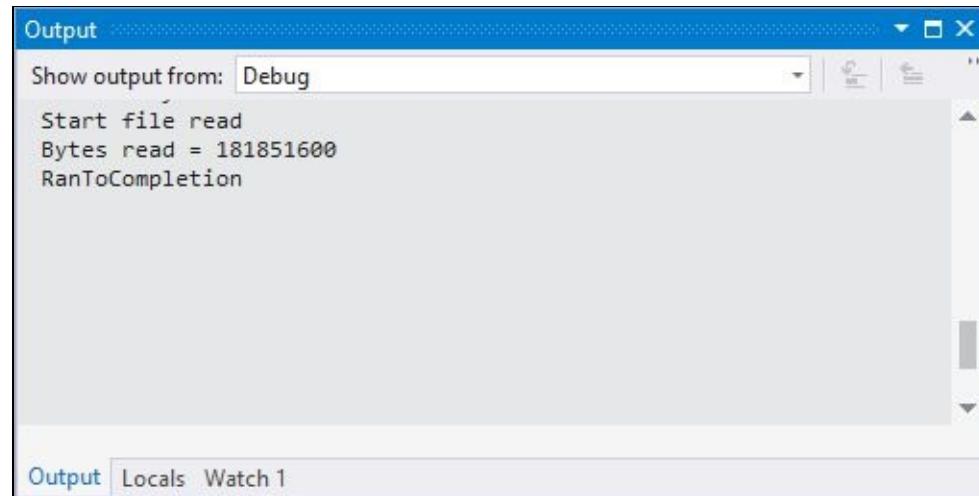

# How it works...

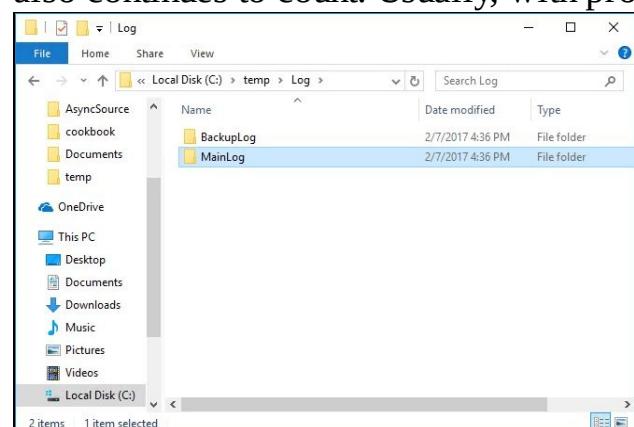

When the Windows form opens up for the first time, you will see that the timer label defaults to Timer Stopped. Click on the Copy Files Async button to start the copy process:

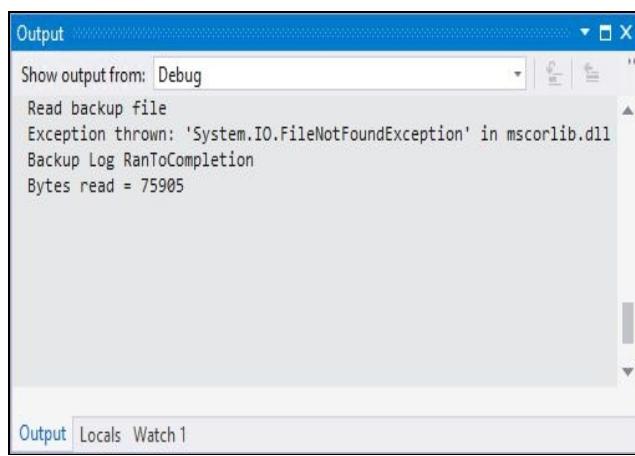

When the application has finished processing, you will see that the large files have been copied to the destination folder:

While the copy process is running, your Windows form remains active and responsive. The timer label also continues to count. Usually, with processes such as these, the form would be unresponsive:

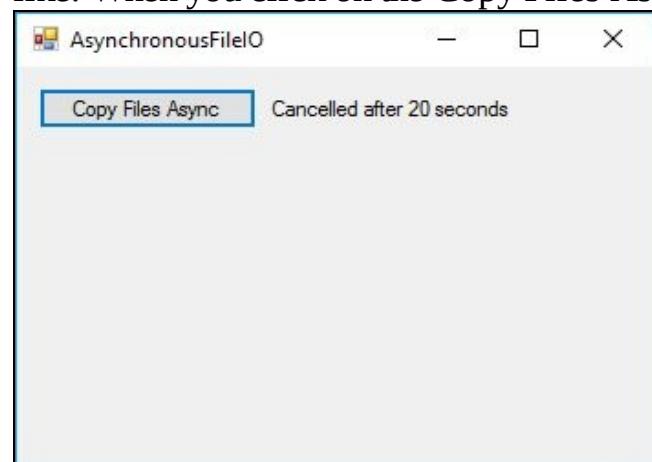

When the files have finished copying, the timer label will display the duration of the async copy process. A fun experiment is to play around with this code to see how much you can optimize it to improve the

copy speed:

The Windows form not only remains responsive, but also allows you to cancel the process whenever you like. When you click on the Copy Files Async button, the text changes to Cancel Async Copy:

Clicking on the Cancel button or sets the `CancellationTokenSource` object to canceled, which in turns stops the async file copy process.

# How to make a custom type serializable?

Serialization is the process by which an object's state is transformed into a set of bytes (depending on the serialization type used, it could be XML, binary, JSON), which can then be saved in a stream (think `MemoryStream` or `FileStream`) or transmitted via WCF or Web API. Making a custom type serializable means that you can apply serialization to custom types by adding the `System.SerializableAttribute`. Examples of custom types are as follows:

- Classes and generic classes
- Structs
- Enums

A real-world example of serialization could be to create a recovery mechanism for a specific object. Think of a workflow scenario. At some point in time, the state of the workflow needs to be persisted. You can serialize the state of that object and store this in a database. When the workflow needs to continue at a future point in time, you can read the object from the database and deserialize it to the exact state as it was before it was persisted to the database.

*Trying to serialize a non-serializable type will result in your code throwing a `SerializationException`.*

# Getting ready

If you are running this example from your console application, ensure that the console application imports the `System` namespace by adding `using System` to the top of your `Program.cs` file. Also ensure that `using System.Runtime.Serialization.Formatters.Binary` is added.

```
[Serializable]<br/> public abstract class Cat<br/> {<br/> // fields<br/> public int Weight;<br/> public int Age; <br/> }

[Serializable]<br/> public class Tiger : Cat<br/> {<br/> public string Trainer;<br/> public bool IsTamed;<br/> }

private static Stream SerializeTiger()<br/> {<br/> Tiger tiger = new Tiger();<br/> tiger.Age = 12;<br/> tiger.IsTamed = false;<br/> tiger.Trainer = "Joe Soap";<br/> tiger.Weight = 120;<br/><br/> MemoryStream stream = new MemoryStream();<br/> BinaryFormatter fmt = new BinaryFormatter();<br/> fmt.Serialize(stream, tiger);<br/> stream.Position = 0;<br/> return stream;<br/> }

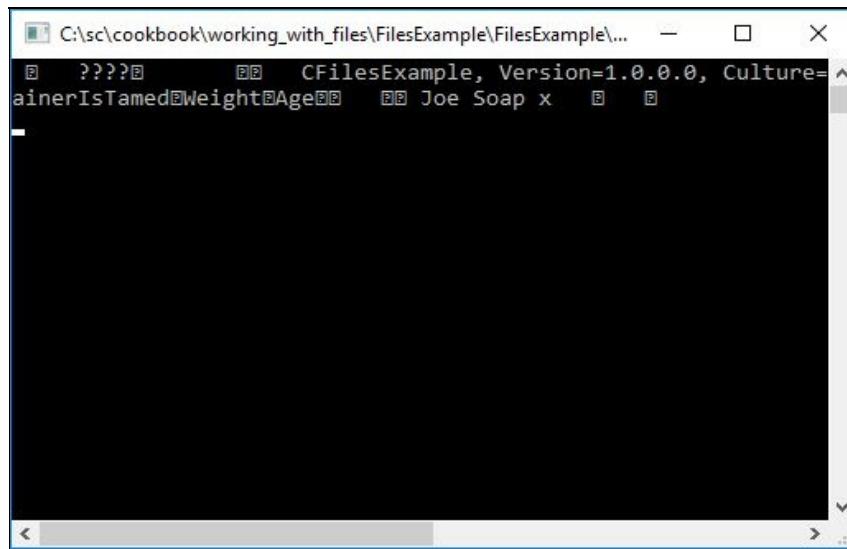

private static void DeserializeTiger(Stream stream)<br/> {<br/> stream.Position = 0;<br/> BinaryFormatter fmt = new BinaryFormatter();<br/> Tiger tiger = (Tiger)fmt.Deserialize(stream);<br/> }

Stream str = SerializeTiger();<br/> WriteLine(new StreamReader(str).ReadToEnd());<br/>
DeserializeTiger(str);
```

# How it works...

When the serialized data is written to the console window, you will see some identifying information. Most of it will, however, look jumbled up. This is because it's binary serialized data that is being displayed.

When this serialized data is deserialized, it is cast back to an object of the type `Tiger`. You can clearly see how the original values of the fields are visible in the deserialized object.

A screenshot of a debugger interface showing a variable named `tiger` of type `Tiger`. A tooltip or context menu is open over the `tiger` variable, displaying its properties:

Age	12
IsTamed	false
Trainer	"Joe Soap"
Weight	120

# Using ISerializable for custom serialization to a FileStream

If you want more control over what is serialized, you should implement `ISerializable` on your object. This gives a developer complete control over what is serialized. Note that you still need to add the `[ISerializable]` attribute to your object. Lastly, the developer also needs to implement a deserialization constructor. Using `ISerializable`, however, does have a caveat. According to the MSDN, the forward compatibility of your object with newer versions of the .NET Framework and any improvements made to the serialization framework might not be applicable on your object. You also need to implement `ISerializable` on all the derived types of your object.

# Getting ready

We will create a new class that wants to control its own serialization using `ISerializable`. Ensure that your application has the `using System.Runtime.Serialization;` added to the `using` statements.

```

[Serializable]<br/> public class Vehicle : ISerializable<br/> {<br/><br/> }

// Primitive fields<br/> public int VehicleType;<br/> public int EngineCapacity;<br/>
public int TopSpeed;<br/><br/> public Vehicle()<br/> {<br/><br/> }

public void GetObjectData(SerializationInfo info, <br/> StreamingContext context)<br/>
{<br/> info.AddValue("VehicleType", VehicleType);<br/>
info.AddValue("EngineCapacity", EngineCapacity);<br/> info.AddValue("TopSpeed",
TopSpeed);<br/> }

// Deserialization constructor<br/> protected Vehicle(SerializationInfo info,
StreamingContext context)<br/> {<br/> VehicleType = info.GetInt32("VehicleType");
<br/> EngineCapacity = info.GetInt32("EngineCapacity");<br/> TopSpeed =
info.GetInt32("TopSpeed");<br/> }

[Serializable]<br/> public class Vehicle : ISerializable<br/> {<br/> // Primitive fields<br/>
public int VehicleType;<br/> public int EngineCapacity;<br/> public int TopSpeed;<br/>
<br/> public Vehicle()<br/> {<br/><br/> }<br/> public void
GetObjectData(SerializationInfo info, <br/> StreamingContext context)<br/> {<br/>
info.AddValue("VehicleType", VehicleType);<br/> info.AddValue("EngineCapacity",
EngineCapacity);<br/> info.AddValue("TopSpeed", TopSpeed);<br/> }<br/><br/> //<br/>
Deserialization constructor<br/> protected Vehicle(SerializationInfo info, <br/>
StreamingContext context)<br/> {<br/> VehicleType = info.GetInt32("VehicleType");
<br/> EngineCapacity = info.GetInt32("EngineCapacity");<br/> TopSpeed =
info.GetInt32("TopSpeed");<br/> }<br/> }

string serializationPath = @"C:\temp\vehicleInfo.dat";<br/> Vehicle vehicle = new
Vehicle();<br/> vehicle.VehicleType = (int)VehicleTypes.Car;<br/> vehicle.EngineCapacity
= 1600;<br/> vehicle.TopSpeed = 230;<br/><br/> if (File.Exists(serializationPath))<br/>
File.Delete(serializationPath);

public enum VehicleTypes<br/> {<br/> Car = 1,<br/> SUV = 2,<br/> Utility = 3<br/> }

using (FileStream stream = new FileStream(serializationPath, <br/> FileMode.Create))
<br/> {<br/> BinaryFormatter fmter = new BinaryFormatter();<br/>
fmter.Serialize(stream, vehicle);<br/> }

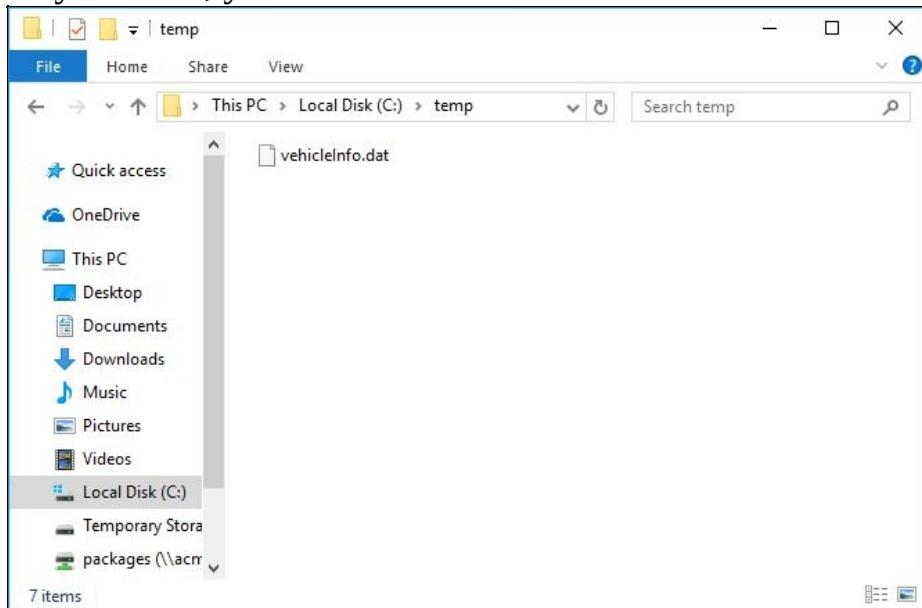

using (FileStream stream = new FileStream(serializationPath, <br/> FileMode.Open))
<br/> {<br/> BinaryFormatter fmter = new BinaryFormatter();<br/> Vehicle
deserializedVehicle = (Vehicle)fmter.Deserialize(stream);<br/> }

```

# How it works...

After you run your code, you will find that the `vehicleInfo.dat` file has been created at the path you

specified:

Opening the file in a text editor will show the serialized information. As you may notice, some of the class information is still visible:

A screenshot of the SciTE text editor. The window title is 'vehicleInfo.dat - SciTE'. The menu bar includes File, Edit, Search, View, Tools, Options, Language, Buffers, Help. The title bar shows '1 vehicleInfo.dat'. The main text area contains the following content:

```
1 NUL SOH NUL NUL NUL NUL yyyy SOH NUL NUL NUL NUL NUL NUL NUL FF STX NUL NUL NUL CFilesE
xample, Version=1.0.0.0, Culture=neutral,
PublicKeyToken=null ENQ SOH NUL NUL FSFilesExample.Program+Vehicle ETX NUL NUL
NUL VT VehicleType SO EngineCapacity BS TopSpeed NUL NUL BS BS BS STX NUL NUL NUL
SOH NUL NUL NUL @ ACK NUL NUL @ NUL NUL NUL VT
```

If we add a breakpoint in the deserialization code and inspect the created `deserializedVehicle` object, you will see that the `Vehicle` state has been *rehydrated* to the state it was before serialization:

```
using (FileStream stream = new FileStream(serializationPath, FileMode.Open))  
{  
    BinaryFormatter fmter = new BinaryFormatter();  
    Vehicle deserializedVehicle = (Vehicle)fmter.Deserialize(stream);  
}
```

≤1ms elapsed

deserializedVehicle {FilesExample.Program.Vehicle}	
EngineCapacity	1600
TopSpeed	230
VehicleType	1

# Using XmlSerializer

From the name you probably guessed that the `XmlSerializer` serializes data into XML. It gives you more control over the XML structure of the serialized data. Typical real-world examples for using this serializer would be to maintain compatibility with XML web services. It is also an easy medium to use when transmitting data using some type of message queuing (such as MSMQ or RabbitMQ).

The default behavior of `XmlSerializer` is to serialize public fields and properties. Using attributes from the `System.Xml.Serialization` namespace, you can control the structure of your XML.

# Getting ready

Since we are going to use `List< >` in this example, ensure that you have added the `using System.Collections.Generic; namespace`. We also want to have more control over the structure of the XML, so also include the `using System.Xml.Serialization; namespace` so that we can use the appropriate attributes. Lastly, for the LINQ query, you will need to add the `using System.Linq; namespace`.

```

public class Student<br/> {<br/> public string StudentName;<br/> public double SubjectMark;<br/> }

[XmlRoot(ElementName = "FundamentalsOfProgramming", <br/> Namespace = "http://serialization")]
public class FundamentalProgramming<br/> {<br/>
[XmlElement(ElementName = "LecturerFullName", <br/> DataType = "string")]
public string Lecturer;<br/><br/> [XmlAttribute]
public double ClassAverage;<br/><br/>
[XmlArray(ElementName = "StudentsInClass", <br/> Namespace = "http://serialization")]
<br/> public List<Student> Students; <br/> }

string serializationPath = @"C:\temp\classInfo.xml";
Student studentA = new Student();
{<br/> StudentName = "John Smith", SubjectMark = 86.4};
<br/> Student studentB = new Student();
{<br/> StudentName = "Jane Smith", SubjectMark = 67.3};
List<Student> students = new List<Student>();
students.Add(studentA);
students.Add(studentB);

FundamentalProgramming subject = new FundamentalProgramming();
subject.Lecturer = "Prof. Johan van Niekerk";
subject.RoomNumber = "Lecture Auditorium A121";
subject.Students = students;
subject.ClassAverage = (students.Sum(mark => mark.SubjectMark) / students.Count());

using (FileStream stream = new FileStream(serializationPath, FileMode.Create))
<br/> {<br/> XmlSerializer xmlSer = new XmlSerializer(typeof(FundamentalProgramming));
xmlSer.Serialize(stream, subject);<br/> }

using (FileStream stream = new FileStream(serializationPath, FileMode.Open))
<br/> {<br/> XmlSerializer xmlSer = new XmlSerializer(typeof(FundamentalProgramming));
FundamentalProgramming fndProg = (FundamentalProgramming)xmlSer.Deserialize(stream);<br/> }

```

# How it works...

When you run the console application, you will find that it creates an XML document at the path you specified in the code. Viewing this XML document, you can see that the XML elements are defined exactly as we specified on the class by using the attributes. Note that the `FundamentalsOfProgramming` root element has the `RoomNumber` field as an attribute. The field `ClassAverage` has been ignored and is not present in the XML. Lastly, you can see how nicely the `List<Student>` object has been serialized to the XML file.

The screenshot shows the SciTE code editor with the file 'classInfo.xml' open. The XML content is as follows:

```
<?xml version="1.0"?>
<FundamentalsOfProgramming xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    RoomNumber="Lecture Auditorium A121" xmlns="http://serialization">
    <LecturerFullName>Prof. Johan van Niekerk</LecturerFullName>
    <StudentsInClass>
        <Student>
            <StudentName>John Smith</StudentName>
            <SubjectMark>86.4</SubjectMark>
        </Student>
        <Student>
            <StudentName>Jane Smith</StudentName>
            <SubjectMark>67.3</SubjectMark>
        </Student>
    </StudentsInClass>
</FundamentalsOfProgramming>
```

On deserialization of the XML, you will notice that the serialized values are displayed. `ClassAverage`; however, does not have a value as it was never serialized to begin with.

The screenshot shows a debugger window with the following code and variable state:

```
using (FileStream stream = new FileStream(serializationPath, FileMode.Open))
{
    XmlSerializer xmlSer = new XmlSerializer(typeof(FundamentalProgramming));
    FundamentalProgramming fndProg = (FundamentalProgramming)xmlSer.Deserialize(stream);
}
```

Variable state for `fndProg`:

- `ClassAverage`: 0
- `Lecturer`: Prof. Johan van Niekerk
- `RoomNumber`: Lecture Auditorium A121
- `Students`: Count = 2

# JSON serializers

Unlike `BinaryFormatter`, JSON serialization serializes data in a human-readable format. Using `XmlSerializer` also produces XML that is human-readable, but JSON serialization produces a smaller data size than `XmlSerializer`. JSON is primarily used to exchange data and can be used with many different programming languages (as can XML).

# Getting ready

From the Tools menu, go to NuGet Package Manager and click on the Manage NuGet Packages for Solution... menu. In the Browse tab, search for Newtonsoft.Json and install the NuGet package. Newtonsoft.Json is a high-performance JSON framework for .NET. Once it is installed, you will see that the reference Newtonsoft.Json has been added to your project, References.

In the `using` statements for your class, add the following namespaces `using Newtonsoft.Json;` and `using Newtonsoft.Json.Linq;` to your code.

```

public class FundamentalProgramming<br/> {<br/> public string Lecturer;<br/> public
double ClassAverage;<br/> public string RoomNumber;<br/> public List<Student>
Students;<br/> }<br/><br/> public class Student<br/> {<br/> public string StudentName;
<br/> public double SubjectMark;<br/> }

string serializationPath = @"C:\temp\classInfo.txt";<br/> Student studentA = new
Student()<br/> {<br/> StudentName = "John Smith"<br/> , SubjectMark = 86.4<br/> };
<br/> Student studentB = new Student()<br/> {<br/> StudentName = "Jane Smith"<br/> ,
SubjectMark = 67.3<br/> };<br/> List<Student> students = new List<Student>();<br/>
students.Add(studentA);<br/> students.Add(studentB);

FundamentalProgramming subject = new FundamentalProgramming();<br/>
subject.Lecturer = "Prof. Johan van Niekerk";<br/> subject.RoomNumber = "Lecture
Auditorium A121";<br/> subject.Students = students;<br/> subject.ClassAverage =
(students.Sum(mark => mark.SubjectMark) / <br/> students.Count());<br/>
WriteLine($"Calculated class average = {subject.ClassAverage}");
```

```

JsonSerializer json = new JsonSerializer();<br/> json.Formatting = Formatting.Indented;
<br/> using (StreamWriter sw = new StreamWriter(serializationPath))<br/> {<br/> using
(JsonWriter wr = new JsonTextWriter(sw))<br/> {<br/> json.Serialize(wr, subject);<br/>
}<br/> }<br/> WriteLine("Serialized to file using JSON Serializer");
```

```

using (StreamReader sr = new StreamReader(serializationPath))<br/> {<br/> string
jsonString = sr.ReadToEnd();<br/> WriteLine("JSON String Read from file");<br/>
JObject jobj = JObject.Parse(jsonString);<br/> IList<double> subjectMarks =
jobj["Students"].Select(<br/> m => (double)m["SubjectMark"]).ToList();<br/> var ave =
subjectMarks.Sum() / subjectMarks.Count();<br/> WriteLine($"Calculated class average
using JObject = {ave}");<br/> }
```

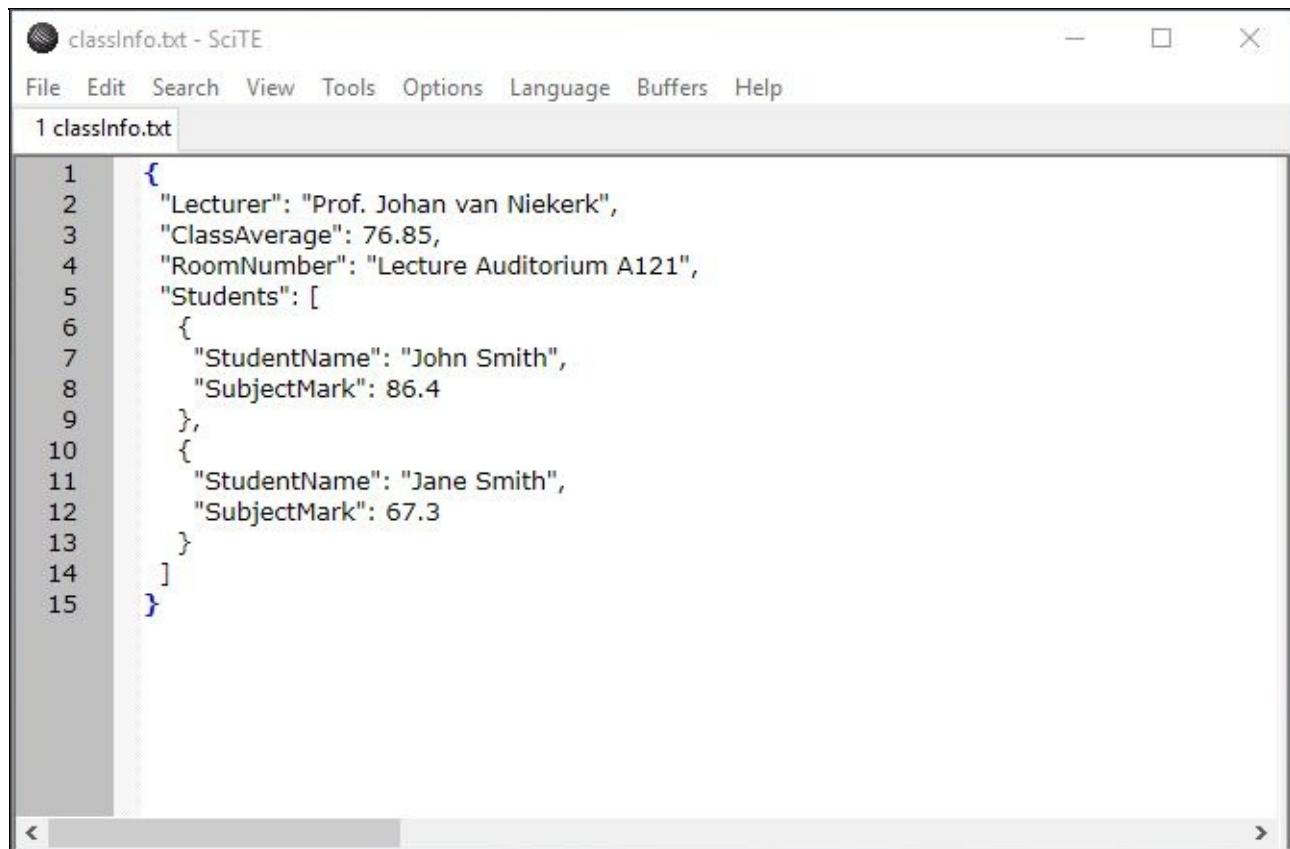

```

using (StreamReader sr = new StreamReader(serializationPath))<br/> {<br/> using
(JsonReader jr = new JsonTextReader(sr))<br/> {<br/> FundamentalProgramming
funProg = json.Deserialize<br/> <FundamentalProgramming>(jr);<br/> }<br/> }
```

# How it works...

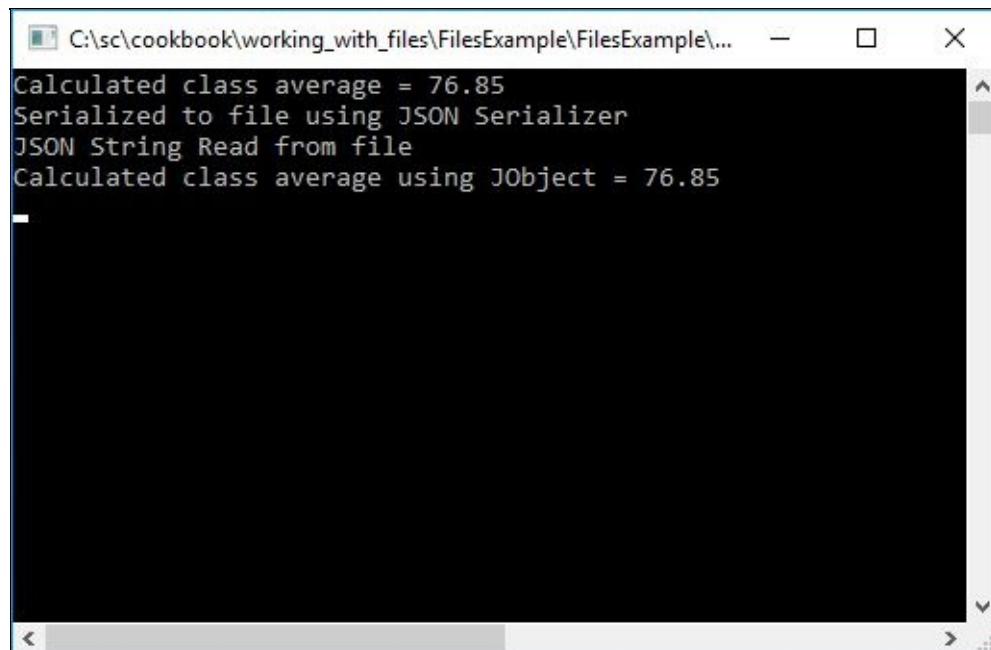

After you run your console application, you can view the file created by the JSON serializer.

The screenshot shows the SciTE code editor with a file named "classInfo.txt". The content of the file is a JSON object representing a class. It includes fields for the lecturer's name, the average mark, the room number, and a list of student marks. The students are represented as an array of objects, each containing their name and mark.

```
1 {
2     "Lecturer": "Prof. Johan van Niekerk",
3     "ClassAverage": 76.85,
4     "RoomNumber": "Lecture Auditorium A121",
5     "Students": [
6         {
7             "StudentName": "John Smith",
8             "SubjectMark": 86.4
9         },
10        {
11            "StudentName": "Jane Smith",
12            "SubjectMark": 67.3
13        }
14    ]
15 }
```

The results of the class average calculation on the class and from the LINQ query on the JSON object are exactly the same.

The screenshot shows a Windows Command Prompt window. The output displays the calculated class average, the file where it was serialized, the JSON string read from the file, and the calculated average using JObject, all of which are identical at 76.85.

```
C:\sc\cookbook\working_with_files\FilesExample\FilesExample>
Calculated class average = 76.85
Serialized to file using JSON Serializer
JSON String Read from file
Calculated class average using JObject = 76.85
```

Lastly, the deserialized object from the JSON text in the file can be seen when adding a break point to the code and inspecting the `funProg` object. As you can see, the object state is the same as before it was serialized to the file.

```

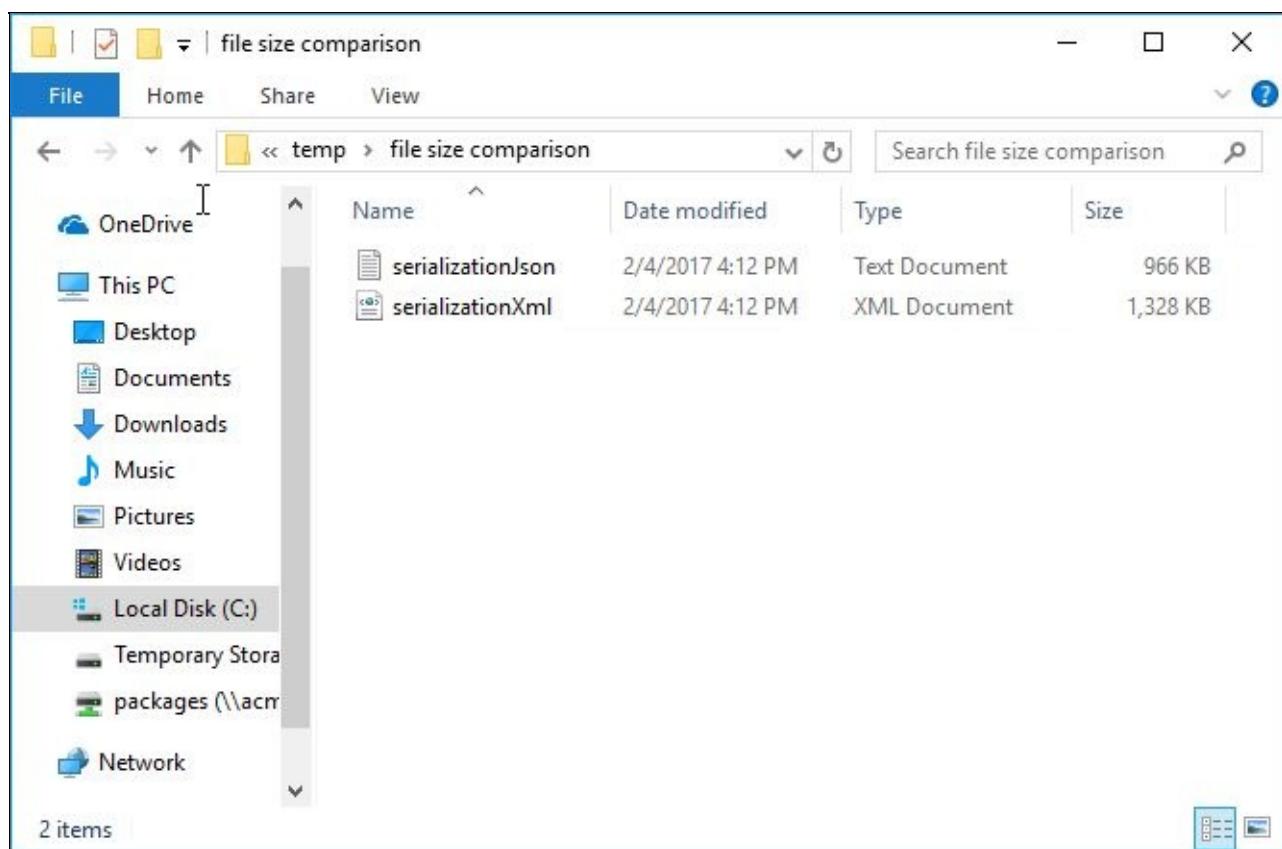

using (StreamReader sr = new StreamReader(serializationPath))
{
    using (JsonReader jr = new JsonTextReader(sr))
    {
        FundamentalProgramming funProg = json.Deserialize< FundamentalProgramming>(jr);
    }
}
//json.Deserialize()

```

funProg {FilesExample.FundamentalProgramming} ▾

ClassAverage	76.85
Lecturer	Prof. Johan van Niekerk
RoomNumber	Lecture Auditorium A121
Students	Count = 2

Do you remember at the beginning of this recipe I mentioned that JSON produces much less data than XML? I created the `student` class containing 10,000 students in `List<Student>` and serialized using XML and JSON. The comparison between the two file sizes is quite stunning. JSON clearly produces a much smaller file.

# Making Apps Responsive with Asynchronous Programming

This chapter will introduce you to asynchronous programming. It will cover the following recipes:

- Return types of asynchronous functions
- Handling tasks in asynchronous programming
- Exception handling in asynchronous programming

# Introduction

Asynchronous programming is an exciting feature in C#. It allows you to continue program execution on the main thread while a long-running task finishes its execution. When this long-running task is complete, a thread from the thread pool will return to the method containing so that the long-running task can continue execution. The best way to learn and understand asynchronous programming is to experience it. The following recipes will illustrate some of the basics to you.

# Return types of asynchronous functions

In asynchronous programming, the `async` methods can have three possible return types. These are as follows:

- `void`
- `Task`
- `Task<TResult>`

We will take a look at each return type in the following recipe.

# Getting ready

What could be the use of a `void` return type in asynchronous methods? Generally, `void` is used with event handlers. Just bear in mind that `void` returns nothing, so you can't wait for it. Therefore, if you call a `void` return type asynchronous method, your calling code should be able to continue executing code without having to wait for the asynchronous method to complete.

With asynchronous methods that have a return type of `Task`, you can utilize the `await` operator to pause the execution of the current thread until the called asynchronous method has completed. Keep in mind that an asynchronous method that returns a type of `Task` basically does not return an operand. Therefore, if it was written as a synchronous method, it would be a `void` return type method. This statement might be confusing, but it will become clear in the following recipes.

Finally, asynchronous methods that have a `return` statement have a return type of `Task<TResult>`. In other words, if the asynchronous method returns a boolean, you would create an asynchronous method with a return type of `Task<bool>`.

Let's start with the `void` return type asynchronous method.

```
namespace winformAsync <br/> { <br/> public partial class Form1 : Form <br/> { <br/>
public Form1() <br/> { <br/> InitializeComponent(); <br/> } <br/><br/> private void
button1_Click(object sender, EventArgs e) <br/> { <br/><br/> } <br/> } <br/> }

private async void button1_Click(object sender, EventArgs e) <br/> { <br/> }

public class AsyncDemo <br/> { <br/> }

async Task<bool> TaskOfTResultReturning_AsyncMethod() <br/> { <br/> return await
Task.FromResult<bool><br/> (DateTime.IsLeapYear(DateTime.Now.Year)); <br/> }

async Task TaskReturning_AsyncMethod() <br/> { <br/> await Task.Delay(5000); <br/>
Console.WriteLine("5 second delay"); <br/> }

public async Task LongTask() <br/> { <br/> bool isLeapYear = await
TaskOfTResultReturning_AsyncMethod(); <br/> Console.WriteLine($""
{DateTime.Now.Year} {(isLeapYear ? " is " : " is not ")} a leap year"); <br/> await
TaskReturning_AsyncMethod(); <br/> }

private async void button1_Click(object sender, EventArgs e) <br/> { <br/>
Console.WriteLine("Button Clicked"); <br/> AsyncDemo oAsync = new AsyncDemo();
<br/> await oAsync.LongTask(); <br/> Console.WriteLine("Button Click Ended"); <br/> }

public async Task LongTask() <br/> { <br/> Task<bool> blnIsLeapYear =
TaskOfTResultReturning_AsyncMethod(); <br/><br/> for (int i = 0; i <= 10000; i++)
<br/> { <br/> // Do other work that does not rely on <br/> // blnIsLeapYear before
awaiting <br/> } <br/><br/> bool isLeapYear = await
TaskOfTResultReturning_AsyncMethod(); <br/> Console.WriteLine($""
{DateTime.Now.Year} {(isLeapYear ? " is " : " is not ")} a leap year"); <br/><br/>
Task taskReturnMethhod = TaskReturning_AsyncMethod(); <br/><br/> for (int i = 0; i <=
10000; i++) <br/> { <br/> // Do other work that does not rely on <br/> //
taskReturnMethhod before awaiting <br/> } <br/><br/> await taskReturnMethhod; <br/>
}
```

# How it works...

In the preceding code, we saw the `void` returning type asynchronous method that was used in the `button1_Click` event. We also created a `Task` returning method that returns nothing (that would be a `void` if used in synchronous programming), but returning a `Task` type allows us to `await` the method. Finally, we created a `Task<TResult>` returning method that performs a task and returns the result to the calling code.

# Handling tasks in asynchronous programming

**Task-based Asynchronous Pattern (TAP)** is now the recommended method to create asynchronous code. It executes asynchronously on a thread from the thread pool and does not execute synchronously on the main thread of your application. It allows us to check the task's state by calling the `status` property.

# Getting ready

We will create a task to read a very large text file. This will be accomplished using an asynchronous `Task`. Be sure that you have added the `using System.IO;` namespace to your Windows forms application.

```
public Task<int> ReadBigFile() <br/> { <br/> }
```

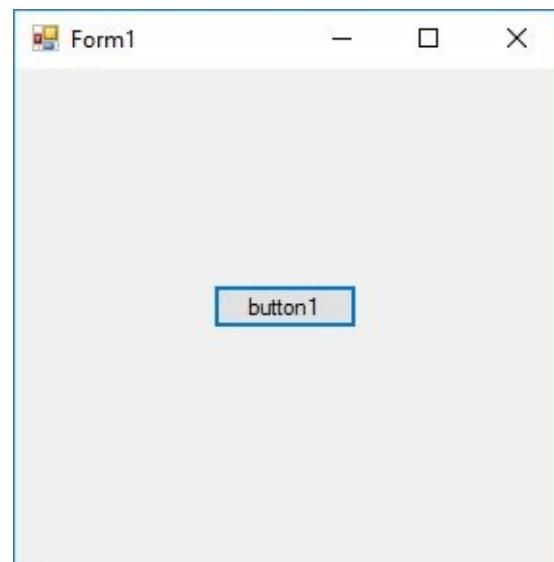

```
public Task<int> ReadBigFile() <br/> { <br/> var bigFile =  
File.OpenRead(@"C:\temp\taskFile\taskFile.txt"); <br/> var bigFileBuffer = new  
byte[bigFile.Length]; <br/> var readBytes = bigFile.ReadAsync(bigFileBuffer, 0,<br/>  
(int)bigFile.Length); <br/><br/> return readBytes; <br/> }
```

```
public Task<int> ReadBigFile() <br/> { <br/> var bigFile =  
File.OpenRead(@"C:\temp\taskFile.txt"); <br/> var bigFileBuffer = new  
byte[bigFile.Length]; <br/> var readBytes = bigFile.ReadAsync(bigFileBuffer, 0, <br/>  
(int)bigFile.Length); <br/> readBytes.ContinueWith(task => <br/> { <br/> if (task.Status  
== TaskStatus.Running) <br/> Console.WriteLine("Running"); <br/> else if (task.Status  
== TaskStatus.RanToCompletion) <br/> Console.WriteLine("RanToCompletion"); <br/>  
else if (task.Status == TaskStatus.Faulted) <br/> Console.WriteLine("Faulted"); <br/>  
<br/> bigFile.Dispose(); <br/> }); <br/> return readBytes; <br/> }
```

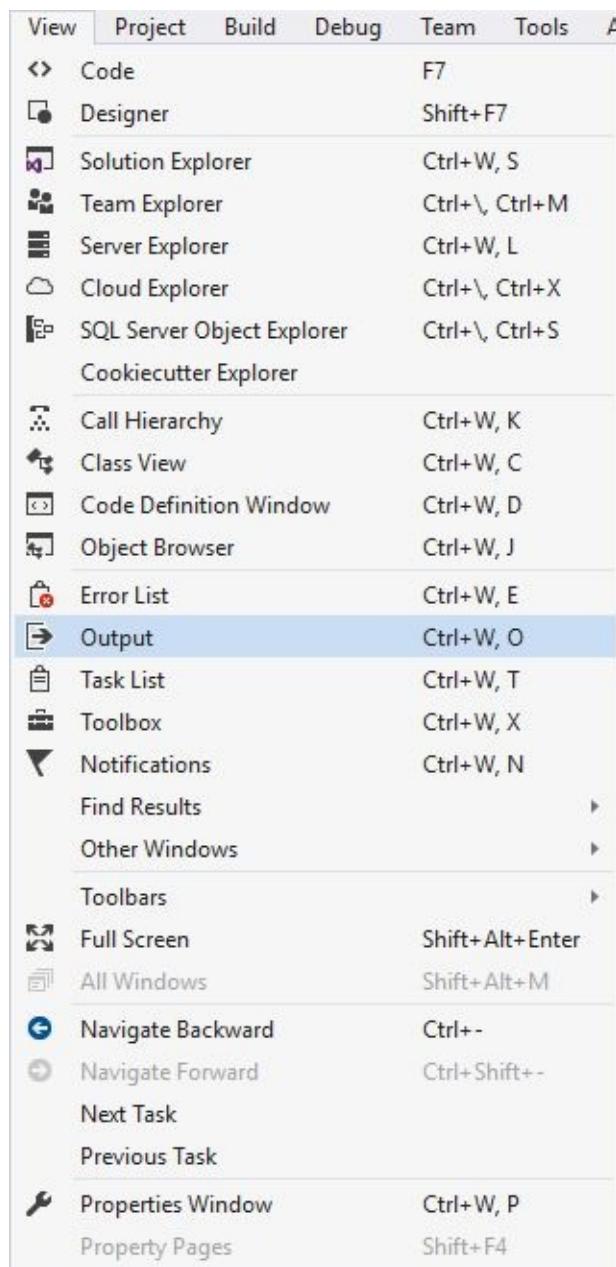

```
namespace winformAsync <br/> { <br/> public partial class Form1 : Form <br/> { <br/>  
public Form1() <br/> { <br/> InitializeComponent(); <br/> } <br/><br/> private void  
button1_Click(object sender, EventArgs e) <br/> { <br/><br/> } <br/> } <br/> }
```

```
private async void button1_Click(object sender, EventArgs e) <br/> { <br/> <br/> }  
  
private async void button1_Click(object sender, EventArgs e) <br/> { <br/>  
Console.WriteLine("Start file read"); <br/> AsyncDemo oAsync = new AsyncDemo();  
<br/> int readResult = await oAsync.ReadBigFile(); <br/> Console.WriteLine("Bytes read  
= " + readResult); <br/> }
```

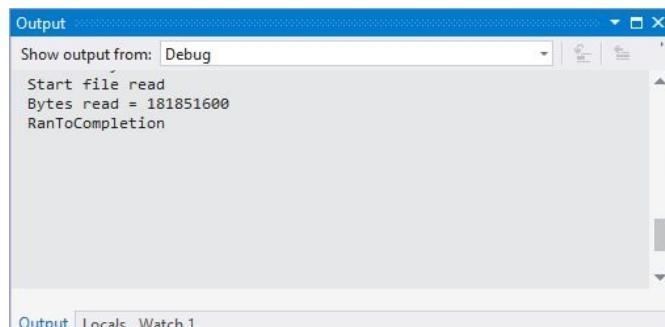

10. Running your application will display the Windows forms application:

## 11. Before clicking on the button1 button, ensure that the Output window is visible:

12. From the View menu, click on the Output menu item or type *Ctrl + W + O* to display the Output window. This will allow us to see the `Console.WriteLine()` outputs that we added to the code in the `AsyncDemo` class and in the Windows application.
13. Clicking on the button1 button will display the outputs to our Output window. Throughout this code execution, the form remains responsive:

Take note, though, that the information displayed in your Output window will differ from

the screenshot. This is because the file you used is different from mine.

# How it works...

The task is executed on a separate thread from the thread pool. This allows the application to remain responsive while the large file is being processed. Tasks can be used in multiple ways to improve your code. This recipe is but one example.

# Exception handling in asynchronous programming

Exception handling in asynchronous programming has always been a challenge. This was especially true in the catch blocks. The following feature (introduced in C# 6.0) allows you to write asynchronous code inside the `catch` and `finally` blocks of your exception handlers.

# Getting ready

The application will simulate the action of reading a log file. Assume that a third-party system always makes a backup of the log file before processing it in another application. While this processing is happening, the log file is deleted and recreated. Our application, however, needs to read this log file on a periodic basis. We therefore need to be prepared for the case where the file does not exist in the location we expect it in. Therefore, we will purposely omit the main log file so that we can force an error.

```
private async Task<int> ReadLog(LogType logType)<br/> {<br/> string filePath =  
String.Empty;<br/> if (logType == LogType.Main)<br/> filePath =  
@"C:\temp\Log\MainLog\taskFile.txt";<br/> else if (logType == LogType.Backup)<br/>  
filePath = @"C:\temp\Log\BackupLog\taskFile.txt";<br/><br/> string enumName =  
Enum.GetName(typeof(LogType), (int)logType);<br/><br/> var bigFile =  
File.OpenRead(filePath);<br/> var bigFileBuffer = new byte[bigFile.Length];<br/> var  
readBytes = bigFile.ReadAsync(bigFileBuffer, 0, <br/> (int)bigFile.Length);<br/> await  
readBytes.ContinueWith(task =><br/> {<br/> if (task.Status ==  
TaskStatus.RanToCompletion)<br/> Console.WriteLine($"{{enumName}} Log  
RanToCompletion");<br/> else if (task.Status == TaskStatus.Faulted)<br/>  
Console.WriteLine($"{{enumName}} Log Faulted");<br/><br/> bigFile.Dispose();<br/> });  
<br/> return await readBytes;<br/> }
```

```
public enum LogType { Main = 0, Backup = 1 }
```

```
public async Task<int> ReadLogFile()<br/> {<br/> int returnBytes = -1;<br/> try<br/>  
<br/> returnBytes = await ReadLog(LogType.Main);<br/> }<br/> catch (Exception ex)  
<br/> {<br/> try<br/> {<br/> returnBytes = await ReadLog(LogType.Backup);<br/> }  
<br/> catch (Exception)<br/> {<br/> throw;<br/> }<br/> }<br/> return returnBytes;<br/>  
}
```

```
namespace winformAsync <br/> { <br/> public partial class Form1 : Form <br/> { <br/>  
public Form1() <br/> { <br/> InitializeComponent(); <br/> } <br/><br/> private void  
button1_Click(object sender, EventArgs e) <br/> { <br/><br/> } <br/> } <br/> }
```

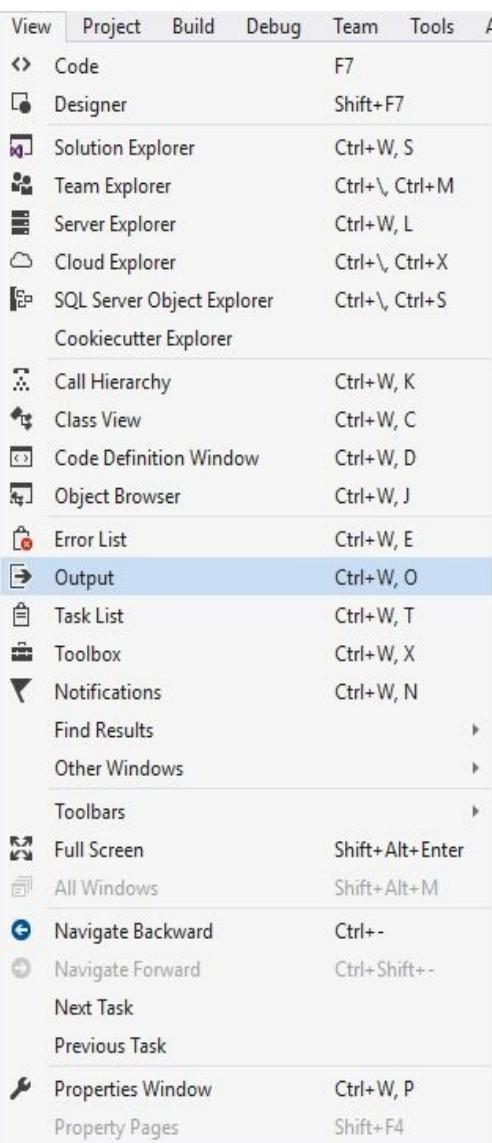

```
private async void button1_Click(object sender, EventArgs e) <br/> { <br/><br/> }
```

```
private async void button1_Click(object sender, EventArgs e) <br/> { <br/>  
Console.WriteLine("Read backup file");<br/> AsyncDemo oAsync = new AsyncDemo();  
<br/> int readResult = await oAsync.ReadLogFile();<br/> Console.WriteLine("Bytes read  
= " + readResult);<br/> }
```

10. Running your application will display the Windows forms application:

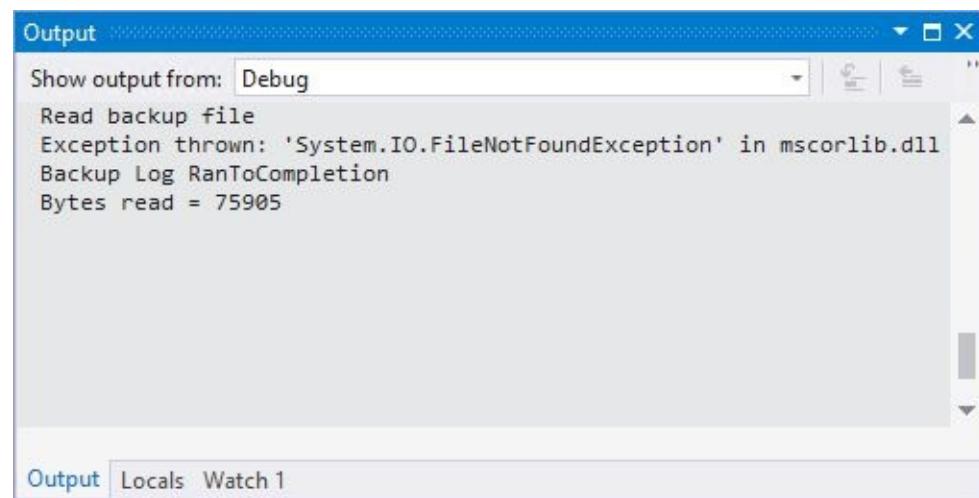

11. Before clicking on the button1 button, ensure that the Output window is visible:

12. From the View menu, click on the Output menu item or type *Ctrl + W + O* to display the Output window. This will allow us to see the `Console.WriteLine()` outputs that

we added to the code in the `AsyncDemo` class and in the Windows application.

13. To simulate a file not found exception, we deleted the file from the `MainLog` folder. You will see that the exception is thrown, and the catch block runs the code to read the backup log file instead:

# How it works...

The fact that we can await in `catch` and `finally` blocks allows developers much more flexibility because asynchronous results can consistently be awaited throughout the application. As you can see from the code we wrote, as soon as the exception was thrown, we asynchronously read the file read method for the backup file.

# High Performance Programming Using Parallel and Multithreading in C#

This chapter takes a look at improving your code's performance using multithreading and parallel programming. In this chapter, we will cover the following recipes:

- Creating and aborting a low-priority background thread
- Increasing the maximum thread pool size
- Creating multiple threads
- Locking one thread until the contended resources are available
- Invoking parallel calls to methods using `Parallel.Invoke`
- Using a parallel foreach loop
- Cancelling a parallel foreach loop
- Catching errors in parallel foreach loops
- Debugging multiple threads

# Introduction

If you can find a single core CPU in a computer today, it will probably mean that you are standing in a museum. Every new computer today utilizes the advantages of multiple cores. Programmers can take advantage of this extra processing power in their own applications. As applications have grown in size and complexity, in many cases they actually need to utilize multithreading.

While not every situation is always suited to the implementation of multithreaded code logic, it is good to know how to use multithreading to improve the performance of your applications. This chapter will take you through the fundamentals of this exciting technology in C# programming.

# Creating and aborting a low-priority background thread

The reason we want to take a look at a background thread specifically is because, by default, all threads created by the main app thread or `Thread` class constructor are foreground threads. So, what exactly separates a foreground thread from a background thread? Well, background threads are identical to foreground threads with the exception that if all foreground threads are terminated, the background threads are stopped too. This is useful if you have a process in your application that must not stop the application from terminating. In other words, while your application is running, the background threads must continue to run.

# Getting ready

We will create a simple application that defines the thread created as a background thread. It will then suspend, resume, and abort the thread.

```
public void DoBackgroundTask(){<br/> {<br/> WriteLine($"Thread<br/>{Thread.CurrentThread.ManagedThreadId} has<br/>a threadstate of<br/>{Thread.CurrentThread.ThreadState} with<br/>{Thread.CurrentThread.Priority}<br/>priority");<br/> WriteLine($"Start thread sleep at {DateTime.Now.Second}<br/>seconds");<br/> Thread.Sleep(3000);<br/> WriteLine($"End thread sleep at<br/>{DateTime.Now.Second} seconds");<br/> }}
```

```
static void Main(string[] args){<br/> {<br/> Demo oRecipe = new Demo();<br/> var backgroundThread = new Thread(oRecipe.DoBackgroundTask);<br/> backgroundThread.IsBackground = true;<br/> backgroundThread.Start();<br/> Thread.Sleep(5000);<br/> }}
```

```
backgroundThread.Priority = ThreadPriority.Lowest;
```

```
Demo oRecipe = new Demo();<br/> var backgroundThread = new Thread(oRecipe.DoBackgroundTask);<br/> backgroundThread.IsBackground = true;<br/> backgroundThread.Priority = ThreadPriority.Lowest;<br/> backgroundThread.Start();<br/> Thread.Sleep(5000);
```

```
public void DoBackgroundTask(){<br/> {<br/> WriteLine($"Thread<br/>{Thread.CurrentThread.ManagedThreadId} has a<br/>threadstate of<br/>{Thread.CurrentThread.ThreadState} with<br/>{Thread.CurrentThread.Priority}<br/>priority");<br/> WriteLine($"Start thread sleep at {DateTime.Now.Second} <br/>seconds");<br/> Thread.CurrentThread.Abort();<br/> Thread.Sleep(3000);<br/> WriteLine($"End thread sleep at {DateTime.Now.Second} seconds");<br/> }}
```

9. When you run your console application, you will see that the thread is aborted before the `Thread.Sleep` method is called. Aborting a thread in this way, however is, generally, not recommended:

Thread 3 has a threadstate of Background with Lowest priority ^  
Start thread sleep at 50 seconds

# **How it works...**

Being able to create a background thread is a great way to work on a different thread from the main thread while not interfering with the process of the main application thread. Another added benefit is that the background thread is terminated as soon as the main application thread is completed. This process ensures that your application will terminate gracefully.

# Increasing the maximum thread pool size

The thread pool in .NET resides in the `System.Threading.ThreadPool` class. Generally, there is a lot of discussion around creating your own threads, as opposed to using the thread pool. Popular thinking dictates that the thread pool should be used for brief jobs. This is because the thread pool is limited in size. There are many other processes in the system that will use the thread pool. You, therefore, do not want your application to hog all the threads in the thread pool.

The rule is that you can't set the number of maximum worker or completion threads to be fewer than the number of processors on your computer. You are also not allowed to set the maximum worker or completion threads to less than the minimum thread pool size.

# Getting ready

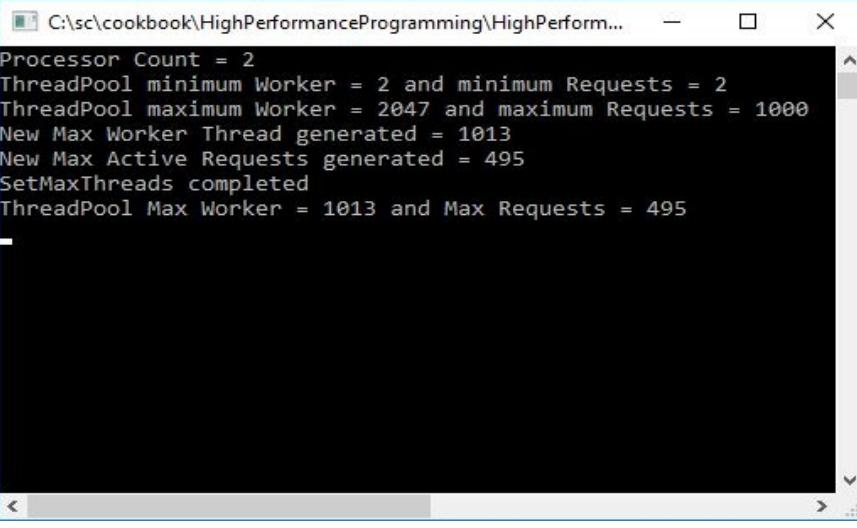

We will read the number of processors on the current computer. Then, we will get the minimum and maximum allowable thread pool size, generate a random number between the minimum and maximum thread pool size, and set the maximum number of threads on the thread pool.

```
public class Demo<br/> {<br/> public void IncreaseThreadPoolSize()<br/> {<br/> int  
numberOfProcessors = Environment.ProcessorCount;<br/> WriteLine($"Processor Count  
= {numberOfProcessors}");<br/> }<br/> }  
  
int maxworkerThreads; <br/> int maxconcurrentActiveRequests; <br/> int  
minworkerThreads; <br/> int minconcurrentActiveRequests; <br/>  
ThreadPool.GetMinThreads(out minworkerThreads, <br/> out  
minconcurrentActiveRequests);<br/> WriteLine($"ThreadPool minimum Worker =  
{minworkerThreads} <br/> and minimum Requests = {minconcurrentActiveRequests}");  
<br/> ThreadPool.GetMaxThreads(out maxworkerThreads, <br/> out  
maxconcurrentActiveRequests);<br/> WriteLine($"ThreadPool maximum Worker =  
{maxworkerThreads} <br/> and maximum Requests =  
{maxconcurrentActiveRequests}");  
  
Random rndWorkers = new Random(); <br/> int newMaxWorker =  
rndWorkers.Next(minworkerThreads, <br/> maxworkerThreads);<br/> WriteLine($"New  
Max Worker Thread generated = {newMaxWorker}"); <br/><br/> Random  
rndConRequests = new Random(); <br/> int newMaxRequests =  
rndConRequests.Next(<br/> minconcurrentActiveRequests,  
maxconcurrentActiveRequests);<br/> WriteLine($"New Max Active Requests generated =  
{newMaxRequests}");  
  
bool changeSucceeded = ThreadPool.SetMaxThreads(<br/> newMaxWorker,  
newMaxRequests); <br/> if (changeSucceeded) { <br/> WriteLine("SetMaxThreads  
completed"); <br/> int maxworkerThreadCount; <br/> int  
maxconcurrentActiveRequestCount; <br/> ThreadPool.GetMaxThreads(out  
maxworkerThreadCount, <br/> out maxconcurrentActiveRequestCount); <br/>  
WriteLine($"ThreadPool Max Worker = {maxworkerThreadCount} <br/> and Max  
Requests = {maxconcurrentActiveRequestCount}"); <br/> } <br/> else <br/>  
WriteLine("SetMaxThreads failed");  
  
public class Demo<br/> { <br/> public void IncreaseThreadPoolSize() <br/> { <br/> int  
numberOfProcessors = Environment.ProcessorCount; <br/> WriteLine($"Processor  
Count = {numberOfProcessors}"); <br/><br/> int maxworkerThreads; <br/> int  
maxconcurrentActiveRequests; <br/> int minworkerThreads; <br/> int  
minconcurrentActiveRequests; <br/> ThreadPool.GetMinThreads(out minworkerThreads,  
<br/> out minconcurrentActiveRequests); <br/> WriteLine($"ThreadPool minimum  
Worker = {minworkerThreads}<br/> and minimum Requests =  
{minconcurrentActiveRequests}"); <br/> ThreadPool.GetMaxThreads(out  
maxworkerThreads, <br/> out maxconcurrentActiveRequests);<br/>
```

```
WriteLine($"ThreadPool maximum Worker = {maxworkerThreads} <br/> and maximum Requests = {maxconcurrentActiveRequests}"); <br/><br/> Random rndWorkers = new Random(); <br/> int newMaxWorker = rndWorkers.Next(minworkerThreads, <br/> maxworkerThreads); <br/> WriteLine($"New Max Worker Thread generated = {newMaxWorker}"); <br/><br/> Random rndConRequests = new Random(); <br/> int newMaxRequests = rndConRequests.Next(<br/> minconcurrentActiveRequests, <br/> maxconcurrentActiveRequests); <br/> WriteLine($"New Max Active Requests generated = <br/> {newMaxRequests}"); <br/><br/> bool changeSucceeded = ThreadPool.SetMaxThreads(<br/> newMaxWorker, newMaxRequests); <br/> if (changeSucceeded) { <br/> WriteLine("SetMaxThreads completed"); <br/> int maxworkerThreadCount; <br/> int maxconcurrentActiveRequestCount; <br/> ThreadPool.GetMaxThreads(out maxworkerThreadCount, <br/> out maxconcurrentActiveRequestCount); <br/> WriteLine($"ThreadPool Max Worker = {maxworkerThreadCount} <br/> and Max Requests = {maxconcurrentActiveRequestCount}"); <br/> } <br/> else <br/> WriteLine("SetMaxThreads failed"); <br/><br/> }
```

```
Demo oRecipe = new Demo(); <br/> oRecipe.IncreaseThreadPoolSize(); <br/> Console.ReadLine();
```

8. Finally, run your console application and take note of the output:

```
C:\sc\cookbook\HighPerformanceProgramming\HighPerform...
Processor Count = 2
ThreadPool minimum Worker = 2 and minimum Requests = 2
ThreadPool maximum Worker = 2047 and maximum Requests = 1000
New Max Worker Thread generated = 1013
New Max Active Requests generated = 495
SetMaxThreads completed
ThreadPool Max Worker = 1013 and Max Requests = 495
```

# How it works...

From the console application, we can see that the processor count is 2. The minimum number of thread pool threads, therefore, also equals 2. We then read the maximum thread pool size and generate a random number between the minimum and maximum numbers. Lastly, we set the maximum thread pool size, to our randomly generated minimum and maximum.

While this is only a proof of concept and not something one would do in a production application (setting the thread pool to a random number), it clearly illustrates the ability to set the thread pool to a value specified by the developer.

*The code in this recipe was compiled for 32-bit. Try changing your application to a 64-bit application and run the code again. See the difference a 64-bit makes.*

# **Creating multiple threads**

Sometimes, we need to create multiple threads. Before we can continue, however, we need to wait for these threads to complete doing whatever they need to do. For this, the use of tasks is best suited.

# Getting ready

Make sure that you add the `using System.Threading.Tasks;` statement to the top of your `Recipes` class.

```

public class Demo <br/> { <br/>     public void MultipleThreadWait() <br/> { <br/><br/> }
<br/><br/>     private void RunThread(int sleepSeconds) <br/> { <br/><br/> } <br/> }

Task thread1 = Task.Factory.StartNew(() => RunThread(3)); <br/> Task thread2 =
Task.Factory.StartNew(() => RunThread(5)); <br/> Task thread3 =
Task.Factory.StartNew(() => RunThread(2)); <br/><br/> Task.WaitAll(thread1, thread2,
thread3); <br/> WriteLine("All tasks completed");

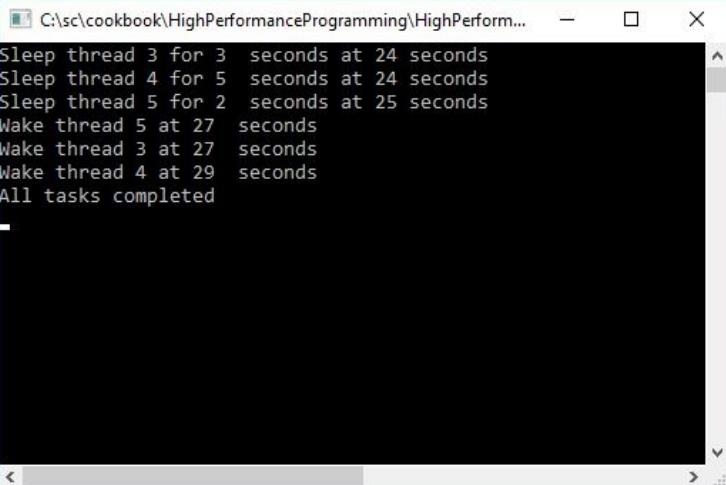

int thread<br/> ID = Thread.CurrentThread.ManagedThreadId; <br/><br/>
WriteLine($"Sleep thread {threadID} for {sleepSeconds} <br/> seconds at
{DateTime.Now.Second} seconds"); <br/> Thread.Sleep(sleepSeconds * 1000); <br/>
WriteLine($"Wake thread {threadID} at {DateTime.Now.Second} <br/> seconds");

public class Demo <br/> { <br/>     public void MultipleThreadWait() <br/> { <br/>         Task
thread1 = Task.Factory.StartNew(() => RunThread(3)); <br/>         Task thread2 =
Task.Factory.StartNew(() => RunThread(5)); <br/>         Task thread3 =
Task.Factory.StartNew(() => RunThread(2)); <br/><br/>         Task.WaitAll(thread1, thread2,
thread3); <br/>         WriteLine("All tasks completed"); <br/>     } <br/><br/>     private void
RunThread(int sleepSeconds) <br/> { <br/>         int threadID =
Thread.CurrentThread.ManagedThreadId; <br/>         WriteLine($"Sleep thread {threadID} for
{sleepSeconds} <br/> seconds at {DateTime.Now.Second} seconds"); <br/>
Thread.Sleep(sleepSeconds * 1000); <br/>         WriteLine($"Wake thread {threadID} at
{DateTime.Now.Second} <br/> seconds"); <br/>     } <br/> }

Demo oRecipe = new Demo(); <br/> oRecipe.MultipleThreadWait(); <br/>
Console.ReadLine();

```

## 6. Run your console application and view the output produced:

```

C:\sc\cookbook\HighPerformanceProgramming\HighPerform...
Sleep thread 3 for 3 seconds at 24 seconds
Sleep thread 4 for 5 seconds at 24 seconds
Sleep thread 5 for 2 seconds at 25 seconds
Wake thread 5 at 27 seconds
Wake thread 3 at 27 seconds
Wake thread 4 at 29 seconds
All tasks completed

```

# How it works...

You will notice that three threads (`thread 3`, `thread 4`, and `thread 5`) are created. These are then paused by making them sleep for various amounts of time. After each thread wakes, the code waits for all three threads to complete before continuing the execution of the application code.

# **Locking one thread until the contended resources are available**

There are instances where we want to give sole access to a process to a specific thread. We can do this using the `lock` keyword. This will, therefore, execute this process in a thread-safe manner. Hence, when a thread runs the process it will gain exclusive access to the process for the duration of the lock scope. If another thread tries to gain access to the process inside the locked code, it will be blocked and have to wait its turn until the lock is released.

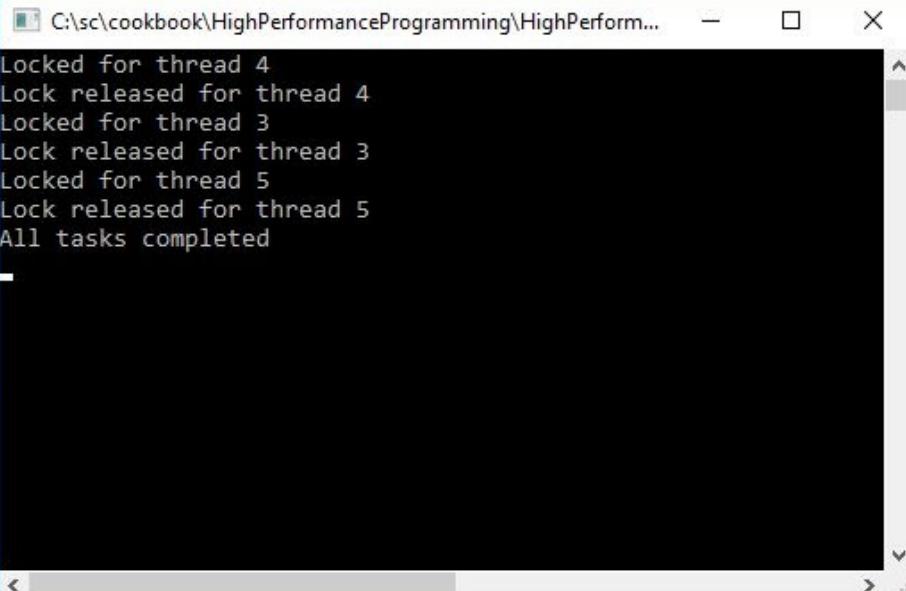

# Getting ready

For this example, we will use tasks. Make sure that you've added the `using System.Threading.Tasks;` statement to the top of your `Demo` class.

```
public class Demo {  
    private object threadLock = new object();  
    public void LockThreadExample() {  
        private void ContendedResource(int sleepSeconds) {  
            Task thread1 = Task.Factory.StartNew(() => ContendedResource(3));  
            Task thread2 = Task.Factory.StartNew(() => ContendedResource(5));  
            Task thread3 = Task.Factory.StartNew(() => ContendedResource(2));  
            Task.WaitAll(thread1, thread2, thread3);  
            WriteLine("All tasks completed");  
  
            int threadID = Thread.CurrentThread.ManagedThreadId;  
            lock (threadLock) {  
                WriteLine($"Locked for thread {threadID}");  
                Thread.Sleep(sleepSeconds * 1000);  
            }  
            WriteLine($"Lock released for thread {threadID}");  
        }  
    }  
}  
  
Demo oRecipe = new Demo();  
oRecipe.LockThreadExample();  
Console.ReadLine();
```

5. Run the console application and look at the information output to the console window:

The screenshot shows a Windows Command Prompt window with a black background and white text. The title bar reads "C:\sc\cookbook\HighPerformanceProgramming\HighPerform...". The window contains the following text:  
Locked for thread 4  
Lock released for thread 4  
Locked for thread 3  
Lock released for thread 3  
Locked for thread 5  
Lock released for thread 5  
All tasks completed

# How it works...

We can see that `thread 4` gained exclusive access to the contended resource. At the same time, `thread 3` and `thread 5` tried to access the contended resource locked by `thread 4`. This then caused the other two threads to wait until `thread 4` had completed and released the lock. The result of this is that the code is executed in an orderly manner, as can be seen in the console window output. Each thread waits its turn until it can access the resource and lock its thread.

# Invoking parallel calls to methods using Parallel.Invoke

`Parallel.Invoke` allows us to execute tasks in (you guessed it) parallel. Sometimes, you need to perform operations simultaneously and, in so doing, speed up the processing. You can, therefore, expect that the total time taken to process the tasks is equal to the longest running process. Using `Parallel.Invoke` is quite easy.

# Getting ready

Make sure that you've added the `using System.Threading.Tasks;` statement to the top of your `Demo` class.

```
public class Demo {  
    public void ParallelInvoke() {  
        private void PerformSomeTask(int sleepSeconds) {  
    }  
}
```

```
    WriteLine($"Parallel.Invoke started at {DateTime.Now.Second} seconds");  
    Parallel.Invoke( () => PerformSomeTask(3), () => PerformSomeTask(5),  
    () => PerformSomeTask(2));  
    WriteLine($"Parallel.Invoke completed at {DateTime.Now.Second} seconds");
```

```
int threadID = Thread.CurrentThread.ManagedThreadId;  
    WriteLine($"Sleep thread {threadID} for {sleepSeconds} seconds");  
    Thread.Sleep(sleepSeconds * 1000);  
    WriteLine($"Thread {threadID} resumed");
```

```
public class Demo {  
    public void ParallelInvoke() {  
        WriteLine($"Parallel.Invoke started at {DateTime.Now.Second} seconds");  
        Parallel.Invoke( () => PerformSomeTask(3), () => PerformSomeTask(5),  
        () => PerformSomeTask(2));  
        WriteLine($"Parallel.Invoke completed at {DateTime.Now.Second} seconds");  
    }  
    private void PerformSomeTask(int sleepSeconds) {  
        int threadID = Thread.CurrentThread.ManagedThreadId;  
        WriteLine($"Sleep thread {threadID} for {sleepSeconds} seconds");  
        Thread.Sleep(sleepSeconds * 1000);  
        WriteLine($"Thread {threadID} resumed");  
    }  
}
```

```
Demo oRecipe = new Demo();  
oRecipe.ParallelInvoke();  
Console.ReadLine();
```

6. Run the console application and look at the output produced in the console window:

```
C:\sc\cookbook\HighPerformanceProgramming\HighPerform...  
Parallel.Invoke started at 39 seconds  
Sleep thread 1 for 3 seconds  
Sleep thread 4 for 2 seconds  
Sleep thread 3 for 5 seconds  
Thread 4 resumed  
Thread 1 resumed  
Thread 3 resumed  
Parallel.Invoke completed at 44 seconds
```

# How it works...

Because we are running all these threads in parallel, we can assume that the longest process will denote the total duration of all the tasks. This means that the total duration of the process will be 5 seconds because the longest task will take 5 seconds to complete (we set `thread 3` to sleep for a maximum of 5 seconds).

As we can see, the time difference between the start and the end of `Parallel.Invoke` is exactly 5 seconds.

# Using a parallel foreach loop

A while ago, during a work retreat (yes, the company I work for is really that cool), Graham Rook, who is one of my colleagues, showed me a parallel `foreach` loop. It certainly speeds up processing a great deal. But here's the rub. It makes no sense to use a parallel `foreach` loop if you're dealing with small amounts of data or little tasks. The parallel `foreach` loop excels when there is bulk processing to do or huge amounts of data to process.

# Getting ready

We will start off by looking at where the parallel `foreach` loop does not perform better than the standard `foreach` loop. For this, we will create a small list of 500 items and just iterate over the list, writing the items to the console window.

For the second example, which illustrates the power of the parallel `foreach` loop, we will use the same list and create a file for each item in the list. The power and benefit of the parallel `foreach` loop will be evident in the second example. You will need to add the `using System.Diagnostics;` and `using System.IO;` namespaces to run this recipe.

```

public class Demo <br/> { <br/> public double ReadCollectionForEach(List<string>
intCollection) <br/> { <br/><br/> } <br/><br/> public double
ReadCollectionParallelForEach(List<string> <br/> intCollection) <br/> { <br/><br/> }
<br/> }

var timer = Stopwatch.StartNew(); <br/> foreach (string integer in intCollection) <br/> {
<br/> WriteLine(integer); <br/> Clear(); <br/> } <br/> return timer.Elapsed.TotalSeconds;

var timer = Stopwatch.StartNew(); <br/> Parallel.ForEach(intCollection, integer => <br/>
{ <br/> WriteLine(integer); <br/> Clear(); <br/> }); <br/> return
timer.Elapsed.TotalSeconds;

public class Demo <br/> { <br/> public double ReadCollectionForEach(List<string>
intCollection) <br/> { <br/> var timer = Stopwatch.StartNew(); <br/> foreach (string
integer in intCollection) <br/> { <br/> WriteLine(integer); <br/> Clear(); <br/> } <br/>
return timer.Elapsed.TotalSeconds; <br/> } <br/><br/> public double
ReadCollectionParallelForEach(List<string> <br/> intCollection) <br/> { <br/> var timer
= Stopwatch.StartNew(); <br/> Parallel.ForEach(intCollection, integer => <br/> { <br/>
WriteLine(integer); <br/> Clear(); <br/> }); <br/> return timer.Elapsed.TotalSeconds;
<br/> } <br/> }

List<string> integerList = new List<string>(); <br/> for (int i = 0; i <= 500; i++) <br/> {
<br/> integerList.Add(i.ToString()); <br/> } <br/> Demo oRecipe = new Demo(); <br/>
double timeElapsed1 = oRecipe.ReadCollectionForEach(integerList); <br/> double
timeElapsed2 = oRecipe.ReadCollectionParallelForEach(<br/> integerList); <br/>
WriteLine($"foreach executed in {timeElapsed1}"); <br/> WriteLine($"Parallel.ForEach
executed in {timeElapsed2}");

public class Demo <br/> { <br/> public void CreateWriteFilesForEach(List<string>
intCollection) <br/> { <br/><br/> } <br/><br/> public void
CreateWriteFilesParallelForEach(List<string> <br/> intCollection) <br/> { <br/><br/> }
<br/> }

WriteLine($"Start foreach File method"); <br/> var timer = Stopwatch.StartNew(); <br/>
foreach (string integer in intCollection) <br/> { <br/><br/> } <br/> WriteLine($"foreach
File method executed in {timer.Elapsed.TotalSeconds} seconds");

string filePath = $"C:\temp\output\ForEach_Log{integer}.txt"; <br/> if
(!File.Exists(filePath)) <br/> { <br/> File.Create(filePath).Dispose(); <br/> using
(StreamWriter sw = new StreamWriter(filePath, false)) <br/> { <br/> sw.WriteLine($"

```

```
{integer}. Log file start: {DateTime.Now.ToUniversalTime().ToString()}); <br/> } <br/>
```

```
WriteLine($"Start Parallel.ForEach File method"); <br/> var timer =  
Stopwatch.StartNew(); <br/> Parallel.ForEach(intCollection, integer => <br/> { <br/>  
<br/> }); <br/> WriteLine($"Parallel.ForEach File method executed in  
{timer.Elapsed.TotalSeconds} seconds");
```

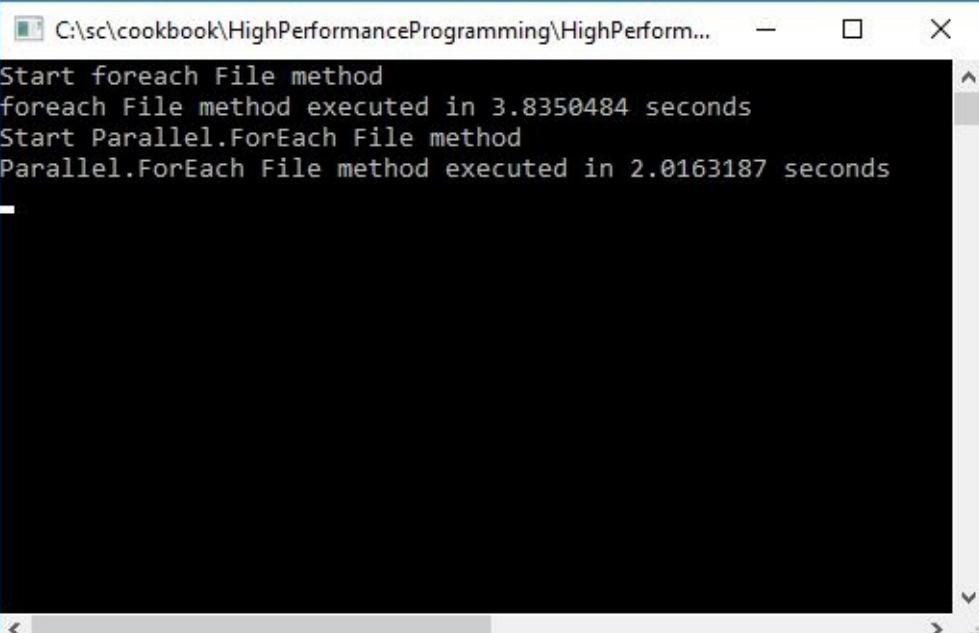

```
string filePath = $"C:\temp\output\ParallelForEach_Log{<br/> integer}.txt"; <br/> if  
(!File.Exists(filePath)) <br/> { <br/> File.Create(filePath).Dispose(); <br/> using  
(StreamWriter sw = new StreamWriter(filePath, false)) <br/> { <br/> sw.WriteLine($"  
{integer}. Log file start: {DateTime.Now.ToUniversalTime().ToString()}); <br/> } <br/>  
}
```

```
public class Demo <br/> { <br/> public void CreateWriteFilesForEach(List<string>  
intCollection) <br/> { <br/> WriteLine($"Start foreach File method"); <br/> var timer =  
Stopwatch.StartNew(); <br/> foreach (string integer in intCollection) <br/> { <br/> string  
filePath = $"C:\temp\output\ForEach_Log{integer}.txt"; <br/> if (!File.Exists(filePath))  
<br/> { <br/> File.Create(filePath).Dispose(); <br/> using (StreamWriter sw = new  
StreamWriter(filePath, false)) <br/> { <br/> sw.WriteLine($"'{integer}'. Log file start:  
{DateTime.Now.ToUniversalTime().ToString()}); <br/> } <br/> } <br/> } <br/>  
WriteLine($"foreach File method executed in {<br/> timer.Elapsed.TotalSeconds}  
seconds"); <br/> } <br/><br/> public void CreateWriteFilesParallelForEach(List<string>  
<br/> intCollection) <br/> { <br/> WriteLine($"Start Parallel.ForEach File method");  
<br/> var timer = Stopwatch.StartNew(); <br/> Parallel.ForEach(intCollection, integer =>  
<br/> { <br/> string filePath = $"C:\temp\output\ParallelForEach_Log <br/>  
{integer}.txt"; <br/> if (!File.Exists(filePath)) <br/> { <br/>  
File.Create(filePath).Dispose(); <br/> using (StreamWriter sw = new  
StreamWriter(filePath, false)) <br/> { <br/> sw.WriteLine($"'{integer}'. Log file start:  
{DateTime.Now.ToUniversalTime().ToString()}); <br/> } <br/> } <br/> }); <br/>  
WriteLine($"Parallel.ForEach File method executed in {timer.Elapsed.TotalSeconds}  
seconds"); <br/> } <br/> }
```

```
List<string> integerList = new List<string>(); <br/> for (int i = 0; i <= 1000; i++) <br/> {  
<br/> integerList.Add(i.ToString()); <br/> } <br/><br/> Demo oRecipe = new Demo();  
<br/> oRecipe.CreateWriteFilesForEach(integerList); <br/>  
oRecipe.CreateWriteFilesParallelForEach(integerList); <br/> ReadLine();
```

14. Finally, when you are ready, make sure that you have the `C:\temp\output` directory and that there aren't any other files in that directory. Run your application and review the output in the console window. This time round, we can see that the

Parallel.ForEach loop has made a huge difference. The performance gain is massive and heralds a 47.42 percent performance increase over the standard foreach loop:

```
C:\sc\cookbook\HighPerformanceProgramming\HighPerform...
Start foreach File method
foreach File method executed in 3.8350484 seconds
Start Parallel.ForEach File method
Parallel.ForEach File method executed in 2.0163187 seconds
```

# How it works...

From the examples used in this recipe, it is clear that use of the parallel `foreach` loop should be considered carefully. If you are dealing with relatively low volumes of data or non-process intensive transactions, the parallel `foreach` loop will not benefit your application's performance much. In some instances, the standard `foreach` loop could be much faster than the parallel `foreach` loop. If, however, you find your application running into performance issues when processing large amounts of data or running processor-intensive tasks, give the parallel `foreach` loop a try. It just might surprise you.

# Cancelling a parallel foreach loop

When dealing with parallel `foreach` loops, the obvious question is how one would terminate the loop prematurely based on a certain condition, such as a timeout. As it turns out, the parallel `foreach` loop is quite easy to terminate prematurely.

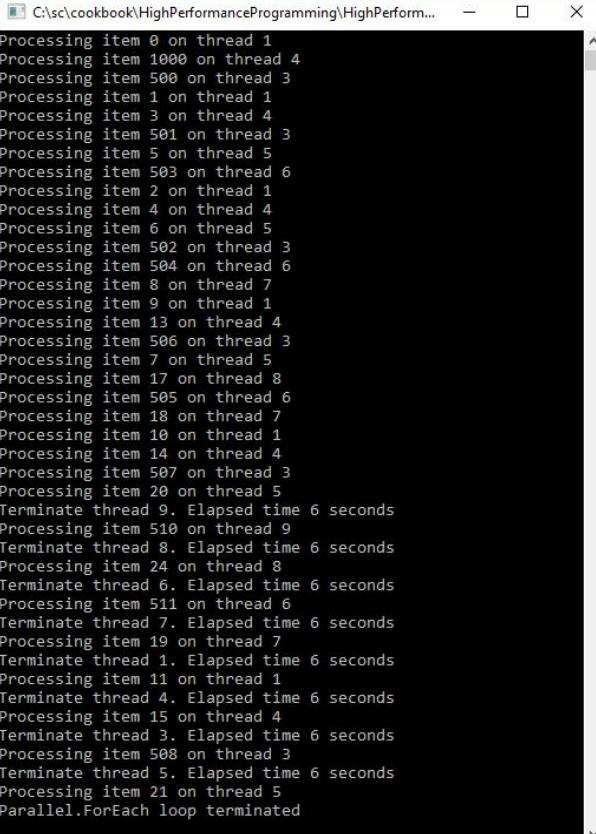

# Getting ready

We will create a method that takes a collection of items and loops through this collection in a parallel `foreach` loop. It will also be aware of a timeout value that, if exceeded, will terminate the loop and exit the method.

```
public class Demo {  
    public void CancelParallelForEach(List<string> intCollection, int timeOut) {  
  
        var timer = Stopwatch.StartNew();  
        Parallel.ForEach(intCollection, (integer, state) => {  
            Thread.Sleep(1000);  
            if (timer.Elapsed.Seconds > timeOut) {  
                WriteLine($"Terminate thread {Thread.CurrentThread.ManagedThreadId}." +  
                    $"\nElapsed time {timer.Elapsed.Seconds} seconds");  
                state.Break();  
            }  
            WriteLine($"Processing item {integer} on thread {Thread.CurrentThread.ManagedThreadId}");  
        });  
    }  
}
```

```
List<string> integerList = new List<string>();  
for (int i = 0; i <= 1000; i++) {  
    integerList.Add(i.ToString());  
}  
Demo oRecipe = new Demo();  
oRecipe.CancelParallelForEach(integerList, 5);  
WriteLine($"Parallel.ForEach loop terminated");  
ReadLine();
```

#### 4. Run your console application and review the output results:

```
C:\sc\cookbook\HighPerformanceProgramming\HighPerform...  
Processing item 0 on thread 1  
Processing item 1000 on thread 4  
Processing item 500 on thread 3  
Processing item 1 on thread 1  
Processing item 3 on thread 4  
Processing item 501 on thread 3  
Processing item 5 on thread 5  
Processing item 503 on thread 6  
Processing item 2 on thread 1  
Processing item 4 on thread 4  
Processing item 6 on thread 5  
Processing item 502 on thread 3  
Processing item 504 on thread 6  
Processing item 8 on thread 7  
Processing item 9 on thread 1  
Processing item 13 on thread 4  
Processing item 506 on thread 3  
Processing item 7 on thread 5  
Processing item 17 on thread 8  
Processing item 505 on thread 6  
Processing item 18 on thread 7  
Processing item 10 on thread 1  
Processing item 14 on thread 4  
Processing item 507 on thread 3  
Processing item 20 on thread 5  
Terminate thread 9. Elapsed time 6 seconds  
Processing item 510 on thread 9  
Terminate thread 8. Elapsed time 6 seconds  
Processing item 24 on thread 8  
Terminate thread 6. Elapsed time 6 seconds  
Processing item 511 on thread 6  
Terminate thread 7. Elapsed time 6 seconds  
Processing item 19 on thread 7  
Terminate thread 1. Elapsed time 6 seconds  
Processing item 11 on thread 1  
Terminate thread 4. Elapsed time 6 seconds  
Processing item 15 on thread 4  
Terminate thread 3. Elapsed time 6 seconds  
Processing item 508 on thread 3  
Terminate thread 5. Elapsed time 6 seconds  
Processing item 21 on thread 5  
Parallel.ForEach loop terminated
```

# How it works...

You can see from the console window output that, as soon as the elapsed time exceeded the timeout value, the parallel loop was notified to cease the execution of iterations beyond the current iteration at the system's earliest convenience. Having this kind of control over the `Parallel.ForEach` loop allows developers to avoid runaway loops, and gives the user control to cancel a loop operation by clicking on a button or automatically having the application terminate when the timeout value has been reached.

# Catching errors in parallel foreach loops

With parallel `foreach` loops, developers can wrap the loop in a `try...catch` statement. Care needs to be taken, however, because the `Parallel.ForEach` will throw an `AggregatedException`, which has the exceptions it encounters over several threads rolled into one.

# Getting ready

We will create a `List<string>` object that contains a collection of machine IP addresses. The `Parallel.ForEach` loop will check the IP addresses to see whether the machines on the other end of the given IPs are alive. It does this by pinging the IP address. The method that performs the `Parallel.ForEach` loop will also be given the minimum required alive machines as an integer value. If the minimum number of machines alive is not met, an exception is thrown.

```

public class Recipes <br/> { <br/> public void CheckClientMachinesOnline(List<string>
ipAddresses, <br/> int minimumLive) <br/> { <br/><br/> } <br/><br/> private bool
MachineReturnedPing(string ip) <br/> { <br/> return false; <br/> } <br/> }

try <br/> { <br/> int machineCount = ipAddresses.Count(); <br/> var options = new
ParallelOptions(); <br/> options.MaxDegreeOfParallelism = machineCount; <br/> int
deadMachines = 0; <br/><br/> Parallel.ForEach(ipAddresses, options, ip => <br/> {
<br/><br/>}); <br/> } <br/> catch (AggregateException aex) <br/> { <br/>
WriteLine("An AggregateException has occurred"); <br/> throw; <br/> }

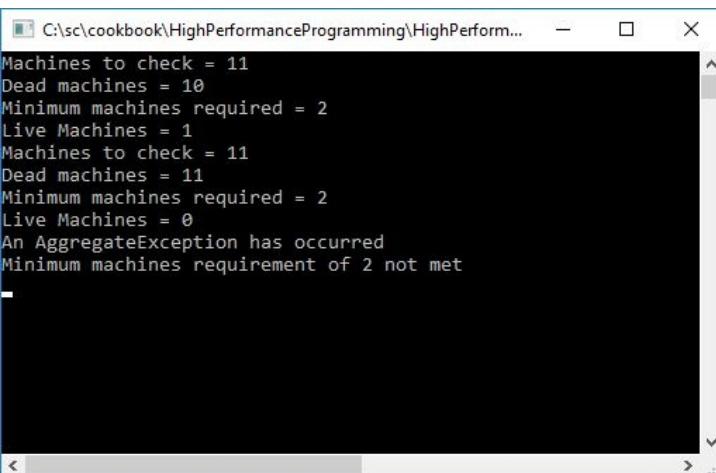

if (MachineReturnedPing(ip)) <br/> { <br/><br/> } <br/> else <br/> { <br/> if
(machineCount - Interlocked.Increment(ref deadMachines) <br/> < minimumLive) <br/>
{ <br/> WriteLine($"Machines to check = {machineCount}"); <br/> WriteLine($"Dead
machines = {deadMachines}"); <br/> WriteLine($"Minimum machines required =
{minimumLive}"); <br/> WriteLine($"Live Machines = {machineCount -
deadMachines}"); <br/> throw new Exception($"Minimum machines requirement of
<br/> {minimumLive} not met"); <br/> } <br/> }

public class Demo <br/> { <br/> public void CheckClientMachinesOnline(List<string>
ipAddresses, <br/> int minimumLive) <br/> { <br/> try <br/> { <br/> int machineCount
= ipAddresses.Count(); <br/> var options = new ParallelOptions(); <br/>
options.MaxDegreeOfParallelism = machineCount; <br/> int deadMachines = 0; <br/>
<br/> Parallel.ForEach(ipAddresses, options, ip => <br/> { <br/> if
(MachineReturnedPing(ip)) <br/> { <br/><br/> } <br/> else <br/> { <br/> if
(machineCount - Interlocked.Increment(<br/> ref deadMachines) < minimumLive) <br/>
{ <br/> WriteLine($"Machines to check = {machineCount}"); <br/> WriteLine($"Dead
machines = {deadMachines}"); <br/> WriteLine($"Minimum machines required =
<br/> {minimumLive}"); <br/> WriteLine($"Live Machines = {machineCount - <br/>
deadMachines}"); <br/> throw new Exception($"Minimum machines requirement <br/>
of {minimumLive} not met"); <br/> } <br/> } <br/> } <br/> } <br/> catch
(AggregateException aex) <br/> { <br/> WriteLine("An AggregateException has
occurred"); <br/> throw; <br/> } <br/> } <br/><br/> private bool
MachineReturnedPing(string ip) <br/> { <br/> return false; <br/> } <br/>

List<string> ipList = new List<string>(); <br/> for (int i = 0; i <= 10; i++) <br/> { <br/>
ipList.Add($"10.0.0.{i.ToString()}"); <br/> } <br/><br/> try <br/> { <br/> Demo oRecipe
= new Demo(); <br/> oRecipe.CheckClientMachinesOnline(ipList, 2); <br/> } <br/> catch
(Exception ex) <br/> { <br/> WriteLine(ex.InnerException.Message); <br/> } <br/>
ReadLine();

```

## 6. Run your application and review the output in the console window:

```
C:\sc\cookbook\HighPerformanceProgramming\HighPerform... - X
Machines to check = 11
Dead machines = 10
Minimum machines required = 2
Live Machines = 1
Machines to check = 11
Dead machines = 11
Minimum machines required = 2
Live Machines = 0
An AggregateException has occurred
Minimum machines requirement of 2 not met
```

Just a point to note. If you have Just My Code enabled, in some cases Visual Studio will break on the line that throws the exception. It might also say that the exception is not handled by the user code. You can just press *F5* to continue. To prevent this from happening, uncheck Enable Just My Code under Tools, Options, Debugging, and General.

# How it works...

From the console window output, you can see that the minimum number of machines required to be online was not achieved. The application then threw an exception and caught it from the `Parallel.ForEach` loop. Being able to handle exceptions in parallel loops such as this one is essential for maintaining the stability of your application by being able to handle exceptions as they occur.

I encourage you to play around a little with the `Parallel.ForEach` loop and drill into some of the inner methods of the `AggregateException` class to really understand it better.

# Debugging multiple threads

Debugging multiple threads in Visual Studio is tricky, especially since these threads are all running at the same time. Luckily, we have a few tools available to us as developers to use to get a better understanding of what is happening in our multithreaded applications.

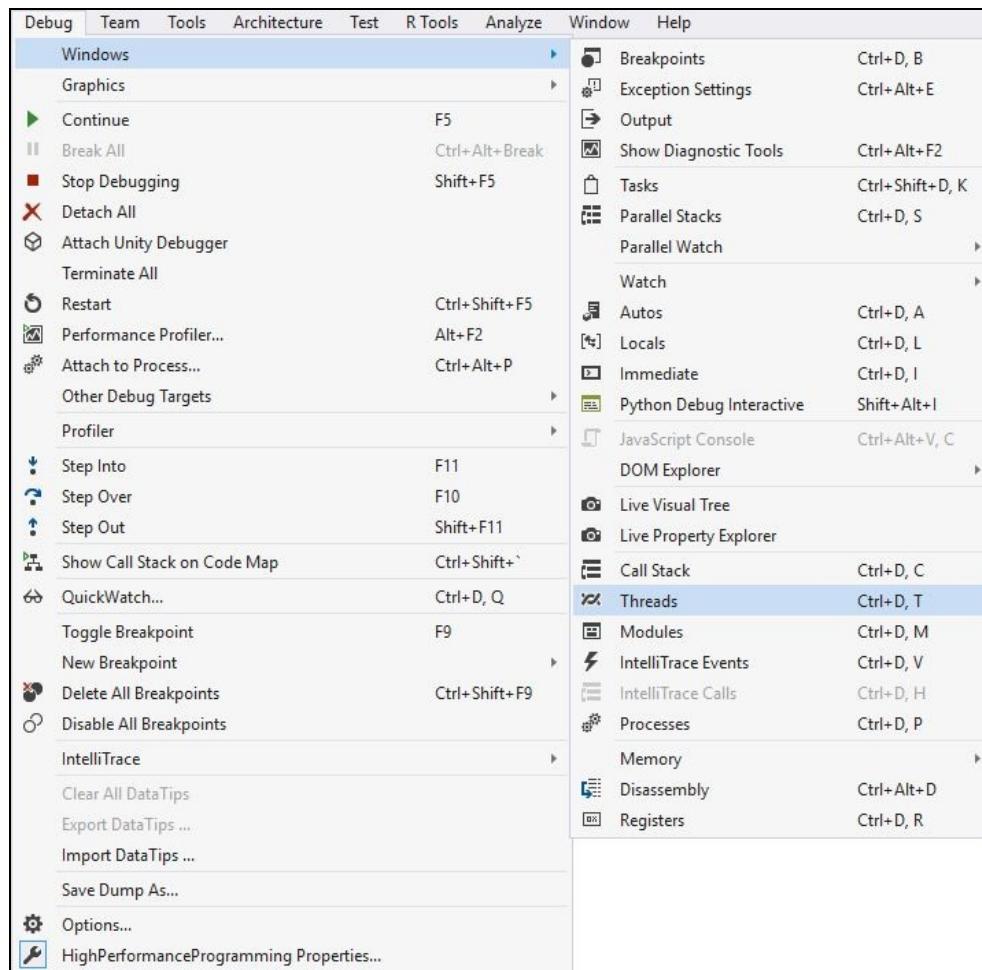

# Getting ready

While debugging multithreaded applications, you can access various windows by navigating to Debug | Windows in Visual Studio.

# How to do it...

1. Start debugging your multithreaded application after adding a break point somewhere in the code. You can access various debugging windows by going to Debug | Windows in Visual Studio:

2. The first window available to you is the Threads window. Access it by going to Debug | Windows in Visual Studio or type *Ctrl + D, T*. In here, you can right-click on a thread to watch and flag it. If you have given your threads names, you will see those names appear in the Name column. To give your thread a name, modify the `LockThreadExample()` method created in an earlier recipe.

```
public void LockThreadExample()
{
    Task thread1 = Task.Factory.StartNew(() => ContendedResource(3));
    Task thread2 = Task.Factory.StartNew(() => ContendedResource(5));
    Task thread3 = Task.Factory.StartNew(() => ContendedResource(2));

    int threadID = Thread.CurrentThread.ManagedThreadId;
    Thread.CurrentThread.Name = $"New Thread{threadID}";

    Task.WaitAll(thread1, thread2, thread3);
    WriteLine("All tasks completed");
}
```

You will also be able to see the currently active thread in the debugger. It will be marked with a yellow arrow. Then, there is the managed ID, which is the same ID you will have used to create the unique thread name earlier on.

The Location column displays the current method that the thread is in. The Threads window

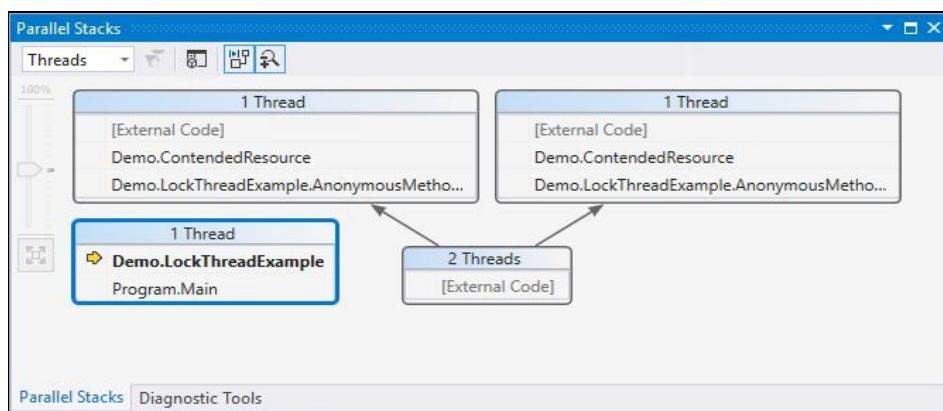

allows you to view the stack of the thread by double-clicking on the Location field. You can also freeze and thaw threads. Freezing stops a thread from executing, while thawing allows the frozen thread to continue as normal.

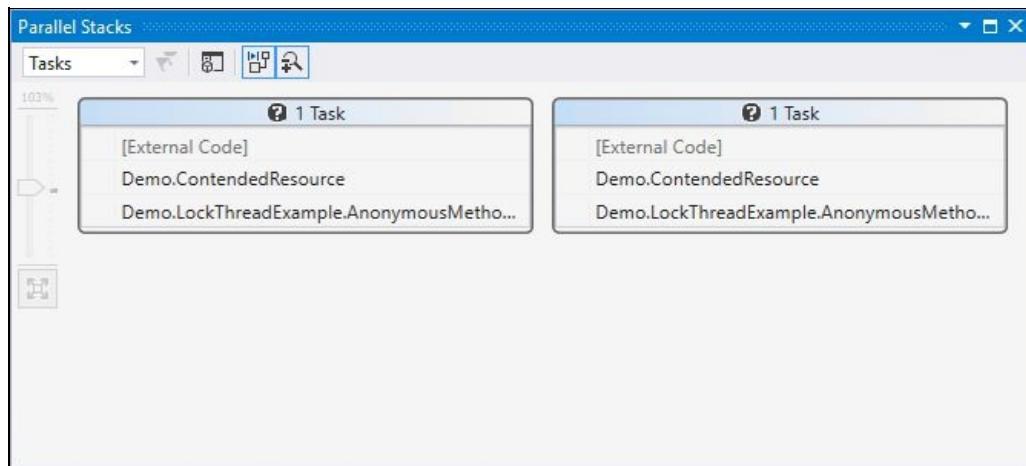

3. The Tasks window can be accessed by going to Debug | Windows or by holding down *Ctrl + Shift + D*, *K*. To see this in action, place a break point in your `LockThreadExample()` method on the line that reads `Task.WaitAll(thread1, thread2, thread3);`. Debug your application again and look at the Status column for each thread created. The status of the task shows the status at that moment, and we can see that the three threads are Active, Blocked, and Scheduled:

	ID	Status	Start Tim...	Duration...	Location	Task
1	1	Blocked	0.000	0.644	HighPerf	HighPerf
2	2	Active	0.000	0.644	[Managed]	Task: <Loca...
3	3	Scheduled	0.000	0.644	[Scheduled]	Task: <Loca...

4. The Parallel Stacks window can be accessed by going to Debug | Windows in Visual Studio or by holding down *Ctrl + D + S* key. Here, you can see a graphical view of the tasks and threads. You can switch between the Threads and Tasks view by making a selection in the drop-down list in the upper-left corner of the Parallel Stacks window:

5. Changing the selection to Tasks will show you the current tasks in the debug session:

6. The next window, undoubtedly my favorite, is the Parallel Watch window. It is in fact identical to the standard Watch window in Visual Studio, but this watches values across all threads in your application. You can type any valid C# expression into Parallel Watch and see the values as they are at that moment in the debug session. Try it out by adding several break points and adding expressions into the Parallel Watch.

# How it works...

Being able to use the debugging tools for multithreaded applications effectively in Visual Studio makes it much easier to understand the structure of your application and helps you identify possible bugs, bottlenecks, and areas of concern.

I encourage you to learn more about these various debugging windows available to you.

# Composing Event-Based Programs Using Reactive Extensions

This chapter deals with **Reactive Extensions (Rx)**. To understand Rx, we will cover the following recipes:

- Installing Rx
- Events versus observables
- Using LINQ to perform queries
- Using schedulers in Rx
- Debugging lambda expressions

# Introduction

Often, during your day-to-day dealings with developing applications in C#, you will have to use asynchronous programming. You might also have to deal with many data sources. Think of a web service that returns the current exchange rates, a Twitter search returning a stream of related data, or even different events generated by multiple computers. Rx provides an elegant solution in the form of the `IObserver<T>` interface.

You use the `IObserver<T>` interface to subscribe to the events. Then, the `IObservable<T>` interface, which maintains a list of `IObserver<T>` interfaces, will notify them of the change of state. In essence, Rx will stick together multiple data sources (social media, RSS feeds, UI events, and so on) that generate data. Rx, therefore, brings these data sources together in one interface. In fact, Rx can be thought of as consisting of three sections:

- **Observables:** The interface that brings together and represents all these datastreams
- **Language-Integrated Query (LINQ):** The ability to use LINQ to query these multiple datastreams
- **Schedulers:** Parameterizing concurrency using schedulers

The question on many minds might be why developers should use (or find a use for) Rx. Here are a few examples where Rx is really useful.

- Creating a search that has an autocomplete function. You don't want the code to perform a search for each value you type into the search area. Rx allows you to throttle the search.
- Making the UI of your application more responsive.
- Being notified when data changes instead of having to poll the data for changes. Think of real-time stock prices.

To keep up to date with Rx, you can take a look at the [GitHub page](https://github.com/Reactive-Extensions/Rx.NET).

# Installing Rx

Before we can begin exploring Rx, we need to install it. The easiest way to do this is using NuGet.

# Getting ready

For this chapter on Rx, we will not create a separate class. All the code will be written in a console application.

# How to do it...

1. Create a console application, and then right-click on your solution and select Manage NuGet Packages for Solution... from the context menu.
2. In the window that is displayed afterwards, type in `System.Reactive` in the search textbox and search for the NuGet installer:

The screenshot shows the NuGet - Solution interface. The search bar at the top contains "System.Reactive". On the left, a list of packages is shown, each with a thumbnail, name, author, download count, version, and a brief description. On the right, a detailed view for "System.Reactive" is expanded, showing its version history (0 versions), project selection options (Project, Rx), and installation status (not installed). Below this, there are sections for Description, Version (3.1.1), Author(s) (.NET Foundation and Contributors), and License (<http://go.microsoft.com/fwlink/?LinkId=261272>). A note at the bottom states that each package is licensed by its owner.

Package	Author	Downloads	Version	Description
<b>System.Reactive</b>	.NET Foundation and Contributors	143K	v3.1.1	Reactive Extensions (Rx) Main Library combining the interfaces, core, LINQ, and platform services libraries.
<b>FluffIt.System.Reactive</b>	Furry Builder	1.19K	v0.1.1.15	A set of extension methods to help in your every day tasks with System.Reactive.
<b>netfx-System.Reactive.EventStream.Implementation.Tests.xUnit</b>	.NET Foundation		v1.0.1.4	xUnit tests for netfx-System.Reactive.EventStream.Implementation
<b>netfx-System.Reactive.Event.Tests.xUnit</b>	.NET Foundation		v1.0.0.2	xUnit tests for netfx-System.Reactive.Event
<b>System.Reactive.Core</b>	.NET Foundation and Contributors	234K	v3.1.1	Reactive Extensions (Rx) Core Library containing base classes and scheduler infrastructure.
<b>System.Reactive.Linq</b>	.NET Foundation and Contributors	214K	v3.1.1	Reactive Extensions (Rx) Query Library used to express complex event processing queries over observable sequences.
<b>System.Reactive.Interfaces</b>	.NET Foundation and Contributors	199K	v3.1.1	Reactive Extensions (Rx) Interfaces Library containing essential interfaces.

3. At the time of writing this book, the last stable release was version 3.1.1. If you have more than a single project, select the projects that you want to install Rx on. Seeing that we only have a single Console application, just select Rx to be installed for the whole project.

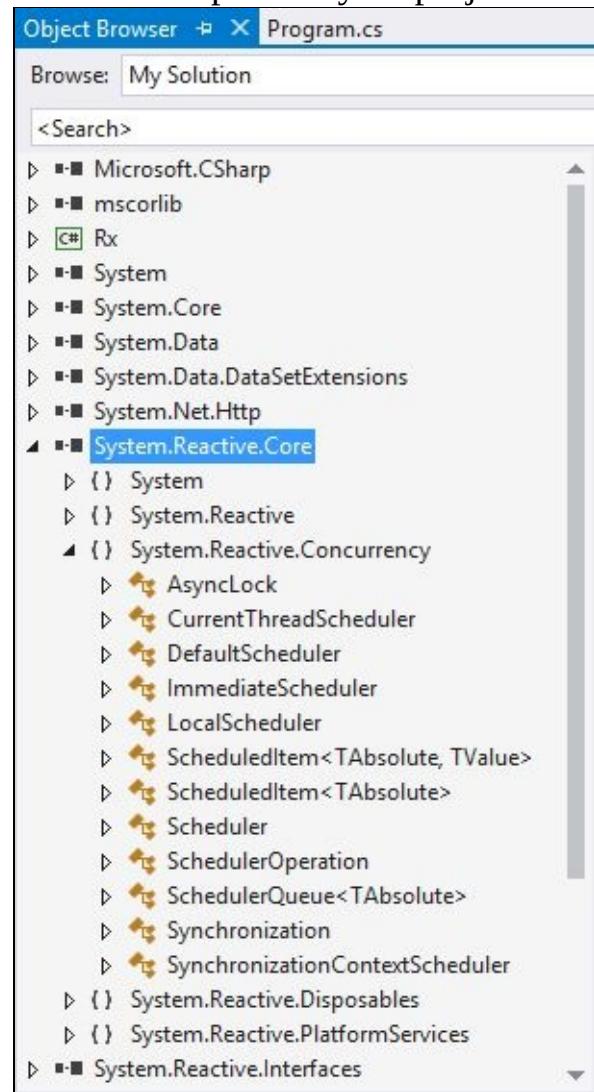

4. The next screen that is displayed is a confirmation dialog box, asking you to confirm the changes to the project. It will show a preview of the changes it will be making to each project. If you are happy with the changes, click on the OK button.
5. A license agreement might be presented to you in the last dialog screen, which you will need to accept. To continue, click on the I Accept button.
6. After the installation is complete, you will see the references added to the Rx under the References node in your project. These are as follows:

- System.Reactive.Core
- System.Reactive.Interfaces
- System.Reactive.Linq
- System.Reactive.PlatformServices

# How it works...

NuGet is by far the easiest way to add additional components to your projects. As you can see from the added references, `System.Reactive` is the main assembly. To gain a better understanding of `System.Reactive`, view the assemblies in Object Browser. To do this, double-click on any of the assemblies in the References option of your project. This will display the Object Browser:

`System.Reactive.Linq` contains all the querying functionality in Rx. You will also notice that `System.Reactive.Concurrency` contains all the schedulers.

# Events versus observables

Being developers, we should all be quite familiar with events. Most developers have been creating events since we started writing code. In fact, if you have even dropped a button control on a form and double-clicked the button to create the method that handles the click of the button, you have created an event. In .NET, we can declare events using the `event` keyword, publish to the event by invoking it, and subscribe to that event by adding a handler to the event. We, therefore, have the following operations:

- Declare
- Publish
- Subscribe

With Rx, we have a similar structure where we declare a datastream, publish data to that stream, and subscribe to it.

# Getting ready

First, we will see how an event works in C#. We will then see the working of an event using Rx and, in doing so, highlight the differences.

```

public class DotNet <br/> { <br/> public string AvailableDatatype { get; set; } <br/> }

class Program <br/> { <br/> // Static action event <br/> static event Action<string> types;
<br/><br/> static void Main(string[] args) <br/> { <br/><br/> } <br/> }

List<DotNet> lstTypes = new List<DotNet>(); <br/> DotNet blnTypes = new DotNet();
<br/> blnTypes.AvailableDatatype = "bool"; <br/> lstTypes.Add(blnTypes); <br/><br/>
DotNet strTypes = new DotNet(); <br/> strTypes.AvailableDatatype = "string"; <br/>
lstTypes.Add(strTypes); <br/><br/> DotNet intTypes = new DotNet(); <br/>
intTypes.AvailableDatatype = "int"; <br/> lstTypes.Add(intTypes); <br/><br/> DotNet
decTypes = new DotNet(); <br/> decTypes.AvailableDatatype = "decimal"; <br/>
lstTypes.Add(decTypes);

types += x => <br/> { <br/> Console.WriteLine(x); <br/> }; <br/><br/> for (int i = 0; i <=
lstTypes.Count - 1; i++) <br/> { <br/> types(lstTypes[i].AvailableDatatype); <br/> } <br/>
<br/> Console.ReadLine();

class Program <br/> { <br/> // Static action event <br/> static event Action<string> types;
<br/> <br/> static void Main(string[] args) <br/> { <br/> List<DotNet> lstTypes = new
List<DotNet>(); <br/> DotNet blnTypes = new DotNet(); <br/>
blnTypes.AvailableDatatype = "bool"; <br/> lstTypes.Add(blnTypes); <br/><br/> DotNet
strTypes = new DotNet(); <br/> strTypes.AvailableDatatype = "string"; <br/>
lstTypes.Add(strTypes); <br/><br/> DotNet intTypes = new DotNet(); <br/>
intTypes.AvailableDatatype = "int"; <br/> lstTypes.Add(intTypes); <br/><br/> DotNet
decTypes = new DotNet(); <br/> decTypes.AvailableDatatype = "decimal"; <br/>
lstTypes.Add(decTypes); <br/><br/> types += x => <br/> { <br/> Console.WriteLine(x);
<br/> }; <br/><br/> for (int i = 0; i <= lstTypes.Count - 1; i++) <br/> { <br/>
types(lstTypes[i].AvailableDatatype); <br/> } <br/><br/> Console.ReadLine(); <br/> }
<br/> }

class Program <br/> { <br/> <br/> static Subject<string> obsTypes = new
Subject<string>(); <br/><br/> static void Main(string[] args) <br/> { <br/><br/> } <br/>
}

// IObservable <br/> obsTypes.Subscribe(x => <br/> { <br/> Console.WriteLine(x); <br/>
}); <br/><br/> // IObserver <br/> for (int i = 0; i <= lstTypes.Count - 1; i++) <br/> {
<br/> obsTypes.OnNext(lstTypes[i].AvailableDatatype); <br/> } <br/><br/>
Console.ReadLine();

class Program <br/> { <br/> static Subject<string> obsTypes = new Subject<string>();
```

```
<br/><br/> static void Main(string[] args) <br/> { <br/> List<DotNet> lstTypes = new  
List<DotNet>(); <br/> DotNet blnTypes = new DotNet(); <br/>  
blnTypes.AvailableDatatype = "bool"; <br/> lstTypes.Add(blnTypes); <br/> <br/> DotNet  
strTypes = new DotNet(); <br/> strTypes.AvailableDatatype = "string"; <br/>  
lstTypes.Add(strTypes); <br/> <br/> DotNet intTypes = new DotNet(); <br/>  
intTypes.AvailableDatatype = "int"; <br/> lstTypes.Add(intTypes); <br/><br/> DotNet  
decTypes = new DotNet(); <br/> decTypes.AvailableDatatype = "decimal"; <br/>  
lstTypes.Add(decTypes); <br/><br/> // IObservable <br/> obsTypes.Subscribe(x => <br/>  
&lt; <br/> Console.WriteLine(x); <br/> ); <br/><br/> // IObserver <br/> for (int i = 0; i <=  
lstTypes.Count - 1; i++) { <br/> obsTypes.OnNext(lstTypes[i].AvailableDatatype);  
<br/> } <br/><br/> Console.ReadLine(); <br/> } <br/> }
```

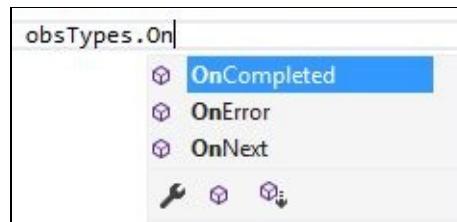

10. When you run your application, you will see the same items are output to the console window, as it did earlier.

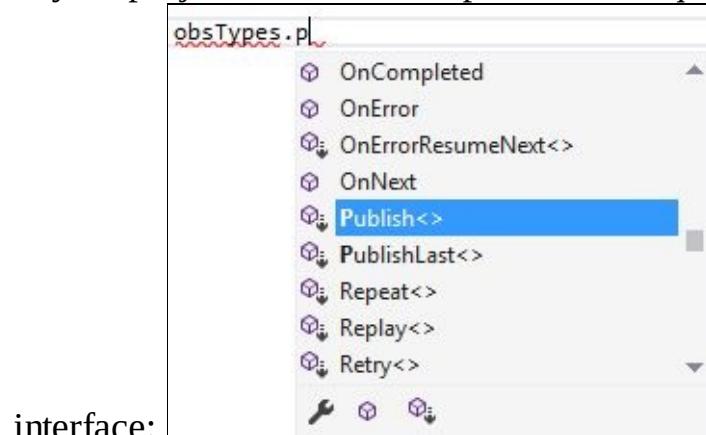

# How it works...

In Rx, we can declare an event stream with the `Subject` keyword. So, we have a source of events that we can publish to using `onNext`. To see those values in the console window, we subscribe to the event stream using `subscribe`.

Rx allows you to have objects that are just publishers or just subscribers. This is because the `IObservable` and `IObserver` interfaces are in fact separate. Also, note that in Rx, the observables can be passed as parameters, returned as results, and stored in variables, which makes them first class.

Rx also allows you to specify that the event stream is completed or that an error occurred. This really sets Rx apart from events in .NET. Also, it is important to note that including the `System.Reactive.Linq` namespace in your project allows developers to write queries over the `Subject` type because a `Subject` is an `IEnumerable`.

This is another feature that sets Rx apart from the events in .NET.

# Using LINQ to perform queries

Rx allows developers to use the `IEnumerable` interface, which represents synchronous datastreams, to write queries using LINQ. To recap, Rx can be thought of as consisting of three sections:

- **Observables:** The interface that brings together and represents all these datastreams
- **Language-Integrated Query (LINQ):** The ability to use LINQ to query these multiple datastreams
- **Schedulers:** Parameterizing concurrency using schedulers

In this recipe, we will be looking at the LINQ functionality of Rx in more detail.

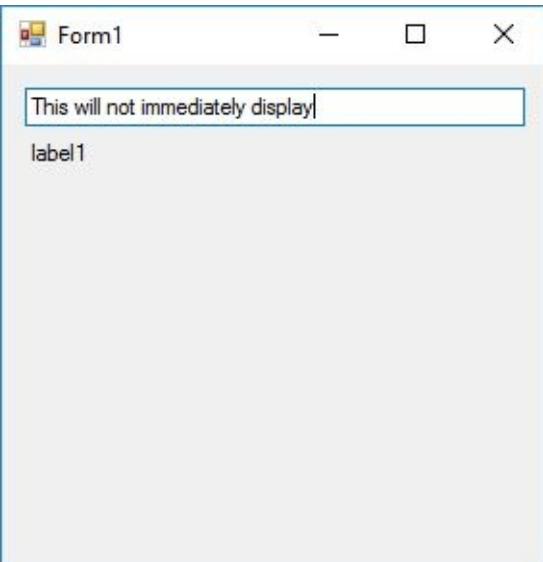

# Getting ready

As observables are just datastreams, we can use LINQ to query them. In the following recipe, we will output text to the screen based on a LINQ query.

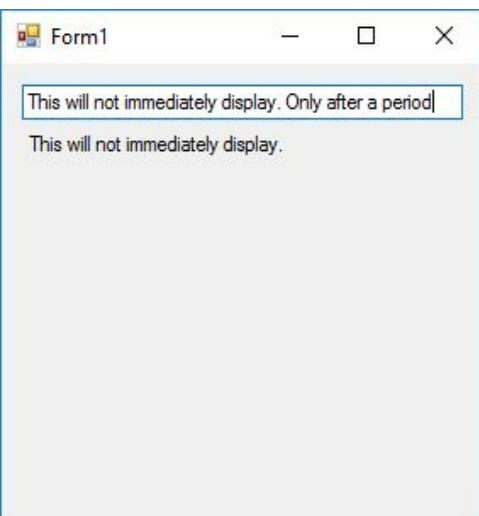

```
private void Form1_Load(object sender, EventArgs e) {  
    var searchTerm = Observable.FromEventPattern<EventArgs>(textBox1, "TextChanged").Select(x =>  
        ((TextBox)x.Sender).Text);  
    searchTerm.Subscribe(trm => label1.Text = trm);  
}
```

```
private void Form1_Load(object sender, EventArgs e) {  
    var searchTerm = Observable.FromEventPattern<EventArgs>(textBox1, "TextChanged").Select(x =>  
        ((TextBox)x.Sender).Text).Where(text => text.EndsWith("."));  
    searchTerm.Subscribe(trm => label1.Text = trm);
```

17. Run your application and start typing in a line of text. You will see that nothing is output to the label control as you type, as was evident in the previous example before we added in our `where` condition:

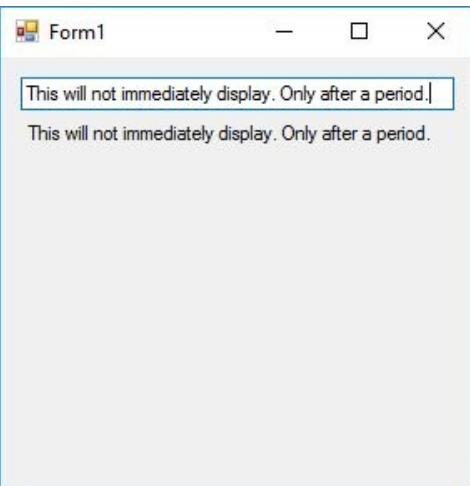

18. Add a period and start adding a second line of text:

19. You will see that only after each period, the text entered is added to the label. Our

Where condition is, therefore, working perfectly:

# How it works...

The LINQ aspect of Rx allows developers to construct observables. Here are some examples:

- `observable.Empty<>`: This returns an empty observable sequence
- `observable.Return<>`: This returns an observable sequence containing a single element
- `observable.Throw<>`: This returns an observable sequence terminating with an exception
- `observable.Never<>`: This returns a non-terminating observable sequence that is infinite in duration

The use of LINQ in Rx allows the developer to manipulate and filter the datastream to return exactly what they need.

# Using schedulers in Rx

Sometimes, we need to have an `Iobservable` subscription run at a specific time. Imagine having to synchronize events across servers in different geographical areas and time zones. You might also need to read data from a queue while preserving the order in which the events occur. Another example would be to perform some kind of I/O task that could take some time to complete. Schedulers come in very handy in these situations.

# Getting ready

Additionally, you can consider reading up more on using schedulers on MSDN. Take a look at [https://msdn.microsoft.com/en-us/library/hh242963\(v=vs.103\).aspx](https://msdn.microsoft.com/en-us/library/hh242963(v=vs.103).aspx).

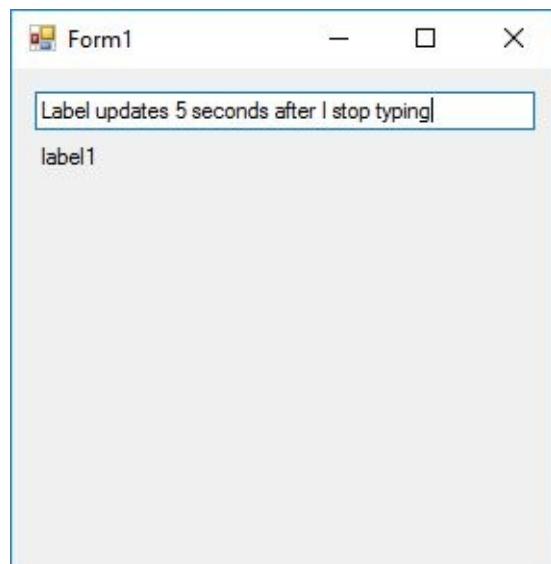

```
private void Form1_Load(object sender, EventArgs e) {  
    var searchTerm = Observable.FromEventPattern<EventArgs>(textBox1, "TextChanged").Select(x =>  
        ((TextBox)x.Sender).Text).Throttle(TimeSpan.FromMilliseconds(5000));  
    searchTerm.Subscribe(trm => label1.Text = trm);  
}
```

<strong>PM> Install-Package System.Reactive.Windows.Forms</strong>

```
searchTerm.ObserveOn(new ControlScheduler(this)).Subscribe(trm => label1.Text =  
    trm);
```

You will notice that we are using the `ObserveOn` method here. What this basically tells the compiler is that the `this` keyword in `new ControlScheduler(this)` is actually a reference to our Windows form. Therefore, `ControlScheduler` will use the Windows forms timers to create the interval to update our UI. The message happens on the correct thread, and we no longer have our cross-thread violation.

8. If you have not added the `System.Reactive.Concurrency` namespace to your project, Visual Studio will underline the `ControlScheduler` line of code with a squiggly line. Pressing `Ctrl + .` (period) will allow you to add the missing namespace.
9. This means that `System.Reactive.Concurrency` contains a scheduler that can talk to Windows forms controls so that it can do the scheduling. Run your application again and start typing some text into your textbox:

10. Around 5 seconds after we stop typing, the throttle condition is fulfilled and the text is output to our label:

Form1

— □ ×

Label updates 5 seconds after I stop typing|

Label updates 5 seconds after I stop typing

# How it works...

What we need to keep in mind here from the code we created is that there is `observeOn` and `subscribe`. You should not confuse the two. In most cases, when dealing with schedulers, you will use `observeOn`. The `observeOn` method allows you to parameterize where the `onNext`, `onCompleted`, and `onError` messages run. With `subscribe`, we parameterize where the actual subscribe and unsubscribe code runs.

We also need to remember that Rx uses the threading timers (`System.Threading.Timer`) as a default, which is why we encountered the cross-thread violation earlier. As you saw though, we used schedulers to parameterize which timer to use. The way schedulers do this is by exposing three components. These are as follows:

- The scheduler's ability to perform some action
- The order in which the action or work to be performed is executed
- A clock that allows the scheduler to have a notion of time

The use of a clock is important because it allows the developer to use timers on remote machines; for example (where there might be a time difference between you and them), to tell them to perform an action at a particular time.

# Debugging lambda expressions

The ability to debug lambda expressions has been around since Visual Studio 2015. This is a fantastic addition to the features of our favorite IDE. It allows us to check the results of a lambda expression on the fly and modify the expression to test different scenarios.

# Getting ready

We will create a very basic lambda expression and change it in the Watch window to produce a different value.

```

public class LambdaExample<br/> {<br/>     public string FavThings { get; set; }<br/> }

List<LambdaExample> MyFavoriteThings = new List<LambdaExample>();<br/>
LambdaExample thing1 = new LambdaExample();<br/>     thing1.FavThings = "Ice-cream";<br/>
MyFavoriteThings.Add(thing1);<br/><br/>     LambdaExample thing2 = new LambdaExample();<br/>     thing2.FavThings = "Summer Rain";<br/>
MyFavoriteThings.Add(thing2);<br/><br/>     LambdaExample thing3 = new LambdaExample();<br/>     thing3.FavThings = "Sunday morning snooze";<br/>
MyFavoriteThings.Add(thing3);

var filteredStuff = MyFavoriteThings.Where(feature =>
feature.FavThings.StartsWith("Sum"));

```

4. Place a breakpoint on the expression and run your application. When the code stops at the breakpoint, you can copy the lambda expression:

```

static void Main(string[] args)
{
    List<LambdaExample> MyFavoriteThings = new List<LambdaExample>();
    LambdaExample thing1 = new LambdaExample();
    thing1.FavoriteFeature = "Ice-cream";
    MyFavoriteThings.Add(thing1);

    LambdaExample thing2 = new LambdaExample();
    thing2.FavoriteFeature = "Summer Rain";
    MyFavoriteThings.Add(thing2);

    LambdaExample thing3 = new LambdaExample();
    thing3.FavoriteFeature = "Sunday morning snooze";
    MyFavoriteThings.Add(thing3);

    var filteredStuff = MyFavoriteThings.Where(feature =>
        feature.FavoriteFeature.StartsWith("Sum"));
}

```

5. Paste the lambda expression `MyFavoriteThings.Where(feature => feature.FavThings.StartsWith("Sum"))` into your Watch windows and change the string in the `StartsWith` method from `Sum` to `Ice`. You will see that the result has changed and now displays an `Ice-cream` string:

## Watch 1

Name	Value
MyFavoriteThings.Where(feature => feature.FavThings.StartsWith("Ice"))	{System.Linq.Enumerable.WhereListT{DebugLambda.LambdaExample}}
[0] FavThings	"Ice-cream"

Find Symbol Results Locals Watch 1

Note that if you are using Visual Studio 2017 RC, debugging lambda expressions will probably not work. You will receive anything from Internal error in the expression evaluator to a message stating Expression cannot contain lambda expression.

# How it works...

In this way, we're able to change and debug a lambda expression easily. This is something that was not possible in the previous versions before Visual Studio 2015. It is obviously of great importance to know this tip when working with these expressions.

Another point to note is that you can do the same thing from the Immediate window in Visual Studio 2017, as well as pinned variables from the lambda expression.

# Exploring .NET Core 1.1

This chapter will explore .NET Core 1.1. We will see what .NET Core is and what you can do with it. We will be looking at:

- Creating a simple .NET Core application and running it on a Mac
- Creating your first ASP.NET Core application
- Publishing your ASP.NET Core application

# Introduction

There is a lot of buzz these days regarding .NET Core. There are really a lot of articles explaining what .NET Core is and what it does. Simply put, .NET Core allows you to create cross-platform applications that run on Windows, Linux, and macOS. It does this by leveraging a .NET Standard Library that targets all these platforms with the exact same code. You can, therefore, use the language and tools you are comfortable with to create applications. It supports C#, VB, and F#, and even allows the use of constructs such as generics, async support, and LINQ. For more information and documentation on .NET Core, go to <https://www.microsoft.com/net/core>.

# **Creating a simple .NET Core application and running it on a Mac**

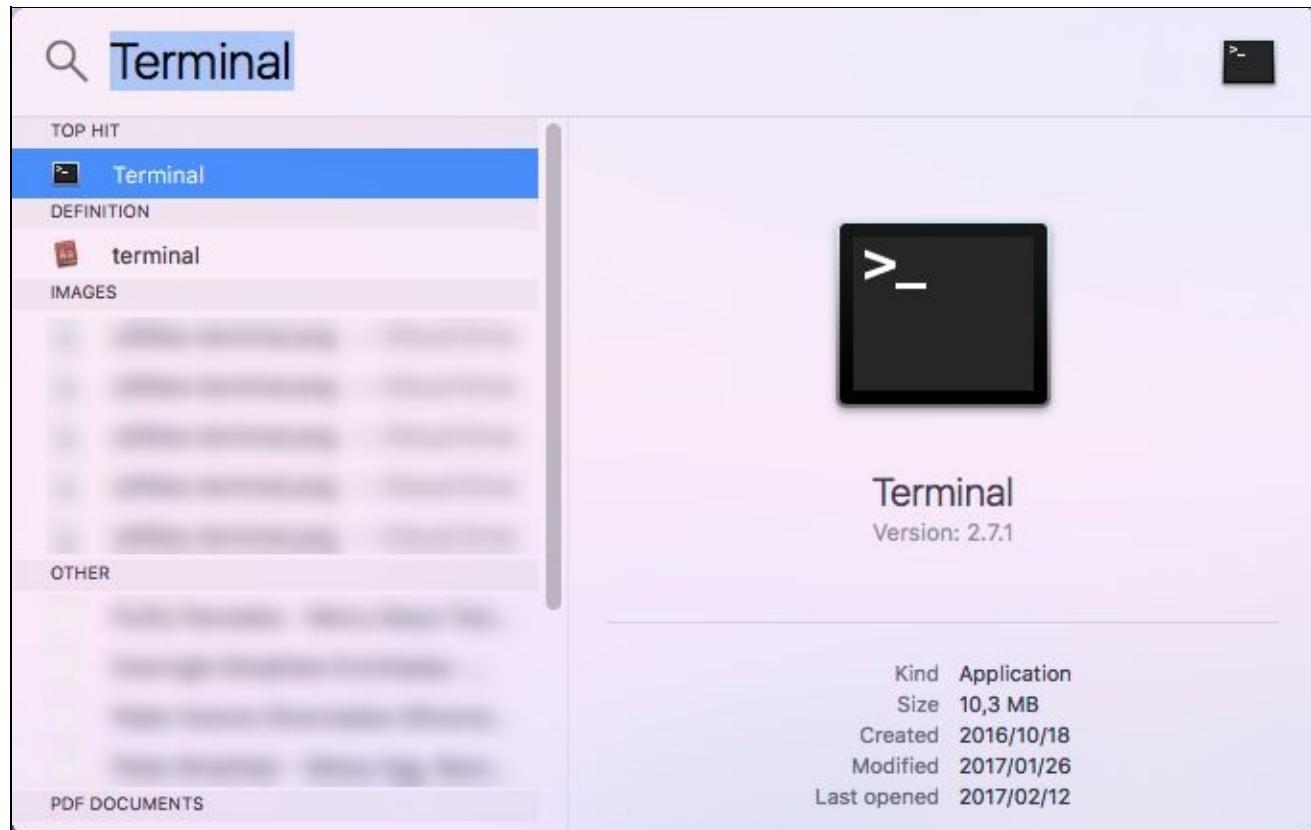

We will take a look at how to create an application on Windows using Visual Studio 2017 and then running that application on a Mac. This kind of application development was previously impossible as you could not run code compiled for Windows on a Mac. .NET Core changes all this.

# Getting ready

You will need access to a Mac in order to run the application you created. I'm using a Mac mini (late 2012) with a 2.5 GHz Intel Core i5 CPU running macOS Sierra with 4GB of memory. In order to use your .NET Core apps on a Mac, there are a few things you need to do:

1. We need to install Homebrew, which is used to get the latest version of OpenSSL. Open the Terminal on your Mac by typing `Terminal` into your Spotlight search:

*The following steps can also be completed by going to <https://www.microsoft.com/net/core#macos> and performing these on your Mac.*

2. Paste the following at the Terminal prompt and press *Enter*:

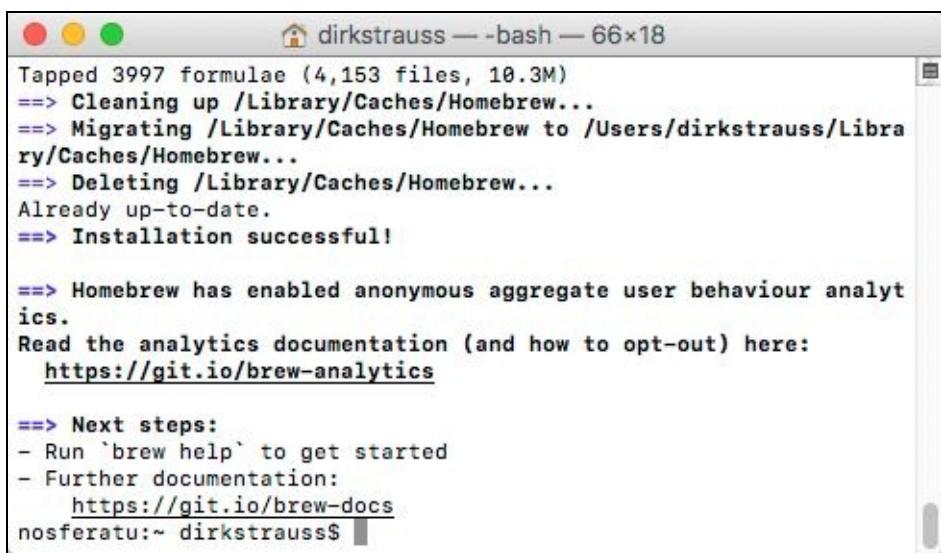

```
| /usr/bin/ruby -e "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/master/install)"
```

3. If the Terminal asks you for your password, enter your password and press *Enter*. You will not see anything as you type. This is normal. Just type your password and press *Enter* to continue.

*The requirements for installing Homebrew are an Intel CPU, OS X 10.10 or higher, **Command Line Tools (CLT)** for Xcode, and a Bourne-compatible shell for installation, such as bash or zsh. Terminal is thus well suited.*

Depending on the speed of your Internet connection and whether you have CLT for Xcode installed, the process of installing Homebrew can take some time to complete. When completed, the Terminal should look as follows:

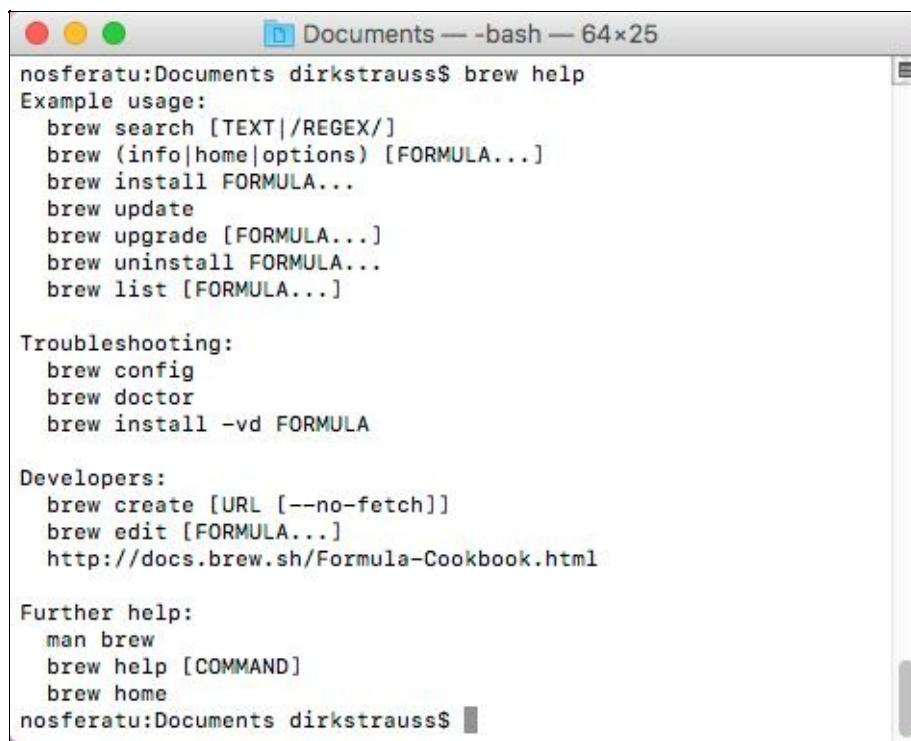

```
dirkstrauss — bash — 66x18
Tapped 3997 formulae (4,153 files, 10.3M)
==> Cleaning up /Library/Caches/Homebrew...
==> Migrating /Library/Caches/Homebrew to /Users/dirkstrauss/Library/Caches/Homebrew...
==> Deleting /Library/Caches/Homebrew...
Already up-to-date.
==> Installation successful!

==> Homebrew has enabled anonymous aggregate user behaviour analytics.
Read the analytics documentation (and how to opt-out) here:
https://git.io/brew-analytics

==> Next steps:
- Run `brew help` to get started
- Further documentation:
  https://git.io/brew-docs
nosferatu:~ dirkstrauss$
```

Typing in `brew help` will show you some useful commands you can use:

```
Documents — bash — 64x25
nosferatu:Documents dirkstrauss$ brew help
Example usage:
  brew search [TEXT|/REGEX/]
  brew (info|home|options) [FORMULA...]
  brew install FORMULA...
  brew update
  brew upgrade [FORMULA...]
  brew uninstall FORMULA...
  brew list [FORMULA...]

Troubleshooting:
  brew config
  brew doctor
  brew install --vd FORMULA

Developers:
  brew create [URL [--no-fetch]]
  brew edit [FORMULA...]
  http://docs.brew.sh/Formula-Cookbook.html

Further help:
  man brew
  brew help [COMMAND]
  brew home
nosferatu:Documents dirkstrauss$
```

Run the following commands one after the other in the Terminal:

- `brew update`
- `brew install openssl`
- `mkdir -p /usr/local/lib`
- `ln -s /usr/local/opt/openssl/lib/libcrypto.1.0.0.dylib /usr/local/lib/`
- `ln -s /usr/local/opt/openssl/lib/libssl.1.0.0.dylib /usr/local/lib/`

We then need to install the .NET Code SDK. From the URL <https://www.microsoft.com/net/core#macos> click on the Download .NET Core SDK button. After the download has completed, click on the `.pkg` file downloaded. Click on the Continue button to install the .NET Core 1.1.0 SDK:

## Welcome to the Microsoft .NET Core 1.1.0 - SDK 1.0.0 Preview 2.1-003177 (x64) Installer

**Introduction**

- License
- Destination Select
- Installation Type
- Installation
- Summary

**Microsoft .NET Core CLI**

.NET Core is a development platform that you can use to build command-line applications, microservices and modern websites. It is open source, cross-platform and is supported by Microsoft. We hope you enjoy using it! If you do, please consider joining the active community of developers that are contributing to the project on GitHub (<https://github.com/dotnet/core>). We happily accept issues and PRs.

This package contains all the tools you will need to start writing applications with .NET Core. It includes the several tools, including the C# compiler and the NuGet package manager, and a copy of .NET Core for both you and the tools to use.

[Go Back](#)[Continue](#)

```
using System;  
class Program  
{  
    static void Main(string[] args)  
    {  
        Console.WriteLine("Hello World!");  
    }  
}  
  
static void Main(string[] args)  
{  
    Console.WriteLine("I can run on Windows,  
Linux and macOS");  
    GetSystemInfo();  
    Console.ReadLine();  
}  
  
private static void GetSystemInfo()  
{  
    var osInfo =  
        System.Runtime.InteropServices.RuntimeInformation.OperatingSystemDescription;  
    Console.WriteLine($"Current OS is: {osInfo}");  
}
```

```
<Project ToolsVersion="15.0"  
xmlns="http://schemas.microsoft.com/developer/msbuild/2003"><br/> <Import  
Project="$(MSBuildExtensionsPath)$(MSBuildToolsVersion)">  
Microsoft.Common.props" /><br/> <PropertyGroup><br/>  
<OutputType>Exe</OutputType><br/>  
<TargetFramework>netcoreapp1.1</TargetFramework><br/> </PropertyGroup><br/>  
<ItemGroup><br/> <Compile Include="***.cs" /><br/> <EmbeddedResource  
Include="***.resx" /><br/> </ItemGroup><br/> <ItemGroup><br/> <PackageReference  
Include="Microsoft.NETCore.App"><br/> <Version>1.1.0</Version><br/>  
</PackageReference><br/> <PackageReference Include="Microsoft.NET.Sdk"><br/>  
<Version>1.0.0-alpha-20161104-2</Version><br/> <PrivateAssets>All</PrivateAssets>  
<br/> </PackageReference><br/> </ItemGroup><br/> <Import  
Project="$(MSBuildToolsPath)Microsoft.CSharp.targets" /><br/> </Project>
```

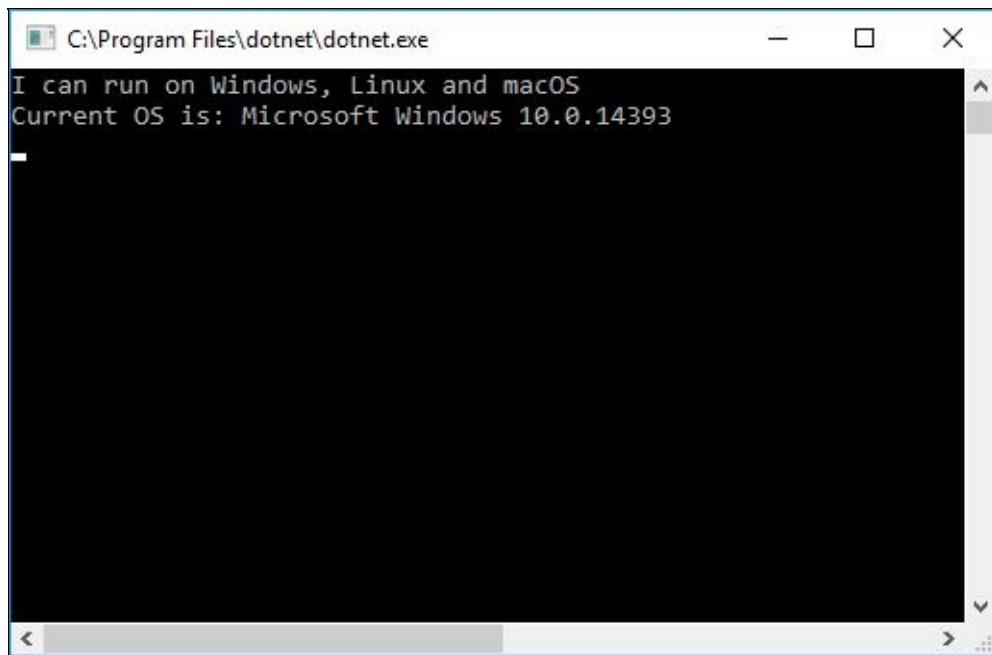

The `<version>` is defined as `1.1.0`.

If you are still running Visual Studio 2017 RC, it would be a good idea to check your installed NuGet packages to see whether there is an update available for your .NET Core version from .NET Core 1.0 to .NET Core 1.1.

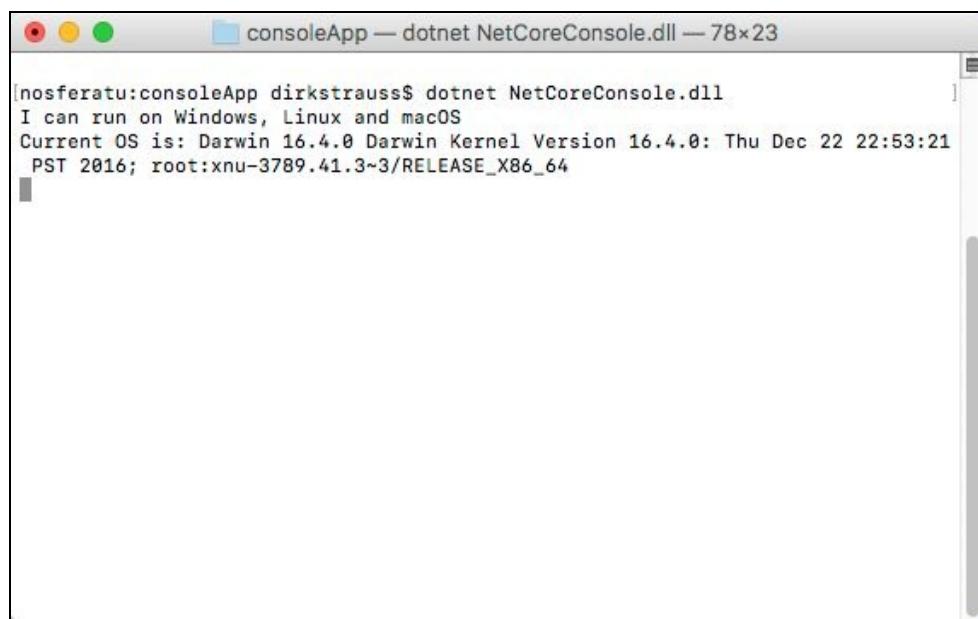

# How it works...

Press **F5** to run your console application. You will see that the OS is displayed in the output:

Go to the `bin` folder of your console application and copy the files to a folder on the desktop of your Mac. Call that folder `consoleApp`. In Terminal, navigate to the folder with the copied files. You can do this by typing the command `cd ./Desktop` and then type `ls` to list the contents of your desktop. Check if the folder you created is listed, and if so, in Terminal type `cd ./consoleApp`. List the contents of the `consoleApp` folder again by typing `ls`. In my case, the DLL was called `NetCoreConsole.dll`. To run the code you wrote earlier, type `dotnet NetCoreConsole.dll` and press *Enter*:

You can see that the code is run and the text output in Terminal.

*If, by any chance, you find that trying to run the `dotnet` command (after installing the .NET Core), results in an error saying `command not found`, try the following. In Terminal type the following at the prompt:*

*Enter: `ln -s /usr/local/share/dotnet/dotnet /usr/local/bin/`, which adds a symbolic link. Running the command should work after this.*

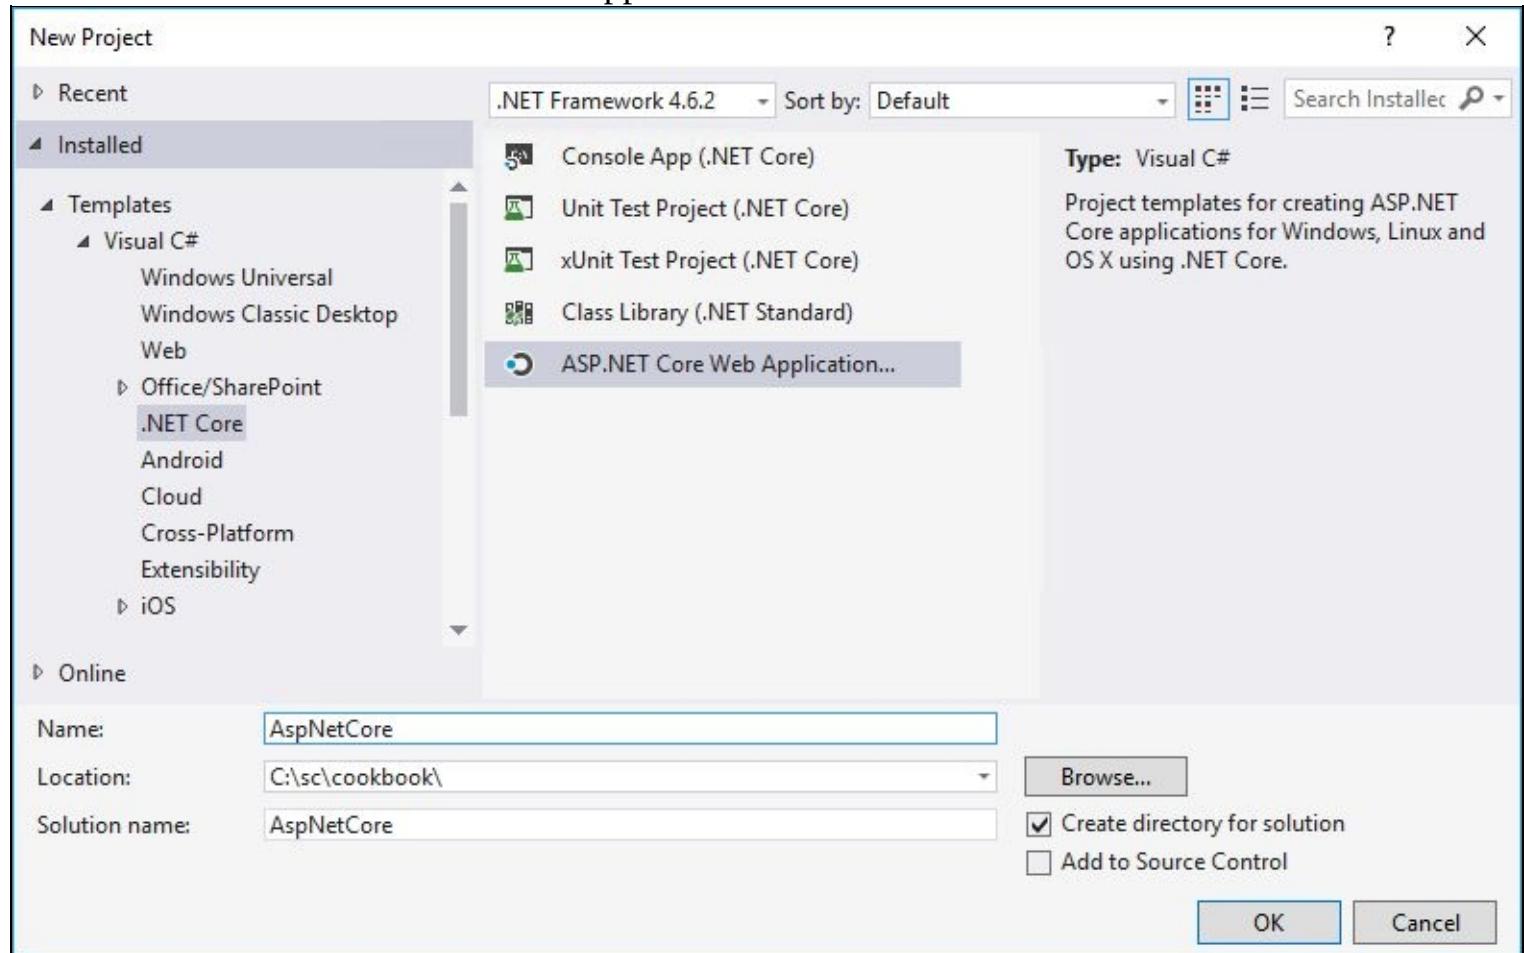

# Creating your first ASP.NET Core application

Let's take a look at building your first ASP.NET Core app. In this recipe, we will just create a very basic ASP.NET Core application and briefly discuss the `Startup` class. Further reading on the subject will be required and is not included in this brief introduction to ASP.NET Core.

# Getting ready

Start off by creating a new project in Visual Studio 2017. Under Visual C#, select the .NET Core node and click on the ASP.NET Core Web Application.... Click on OK:

You will then be presented with the project template selection. You can choose to create an empty application, a Web API (allows you to create an HTTP-based API), or a full Web Application. Select the Empty template, make sure that Host in the cloud is unchecked, and click on OK:

Select a template:

### ASP.NET Core Templates

Empty

Web API

Web Application

An empty project template for creating an ASP.NET Core application. This template does not have any content in it.

[Learn more](#)

[Change Authentication](#)

Authentication: **No Authentication**

Microsoft Azure

Host in the cloud

Enable Container (Docker) Support

Requires [Docker for Windows](#)

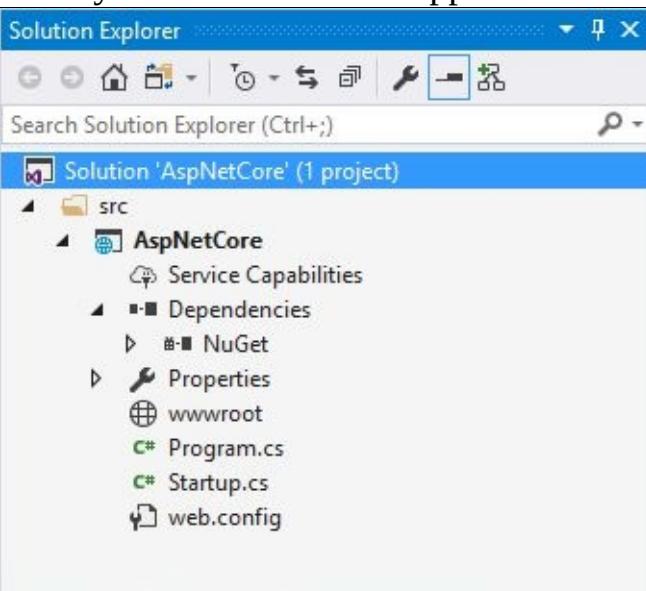

Container support can also be enabled later [Learn more](#)

OK

Cancel

Note how the templates window allows you to enable Docker support. Docker allows you to develop applications inside containers that contain a complete file system and everything else required to run your application. This means that your software will always function exactly the same, regardless of the environment it is in. For more on Docker, visit [www.docker.com](http://www.docker.com).

When your ASP.NET Core application is created, your Solution Explorer will look as follows:

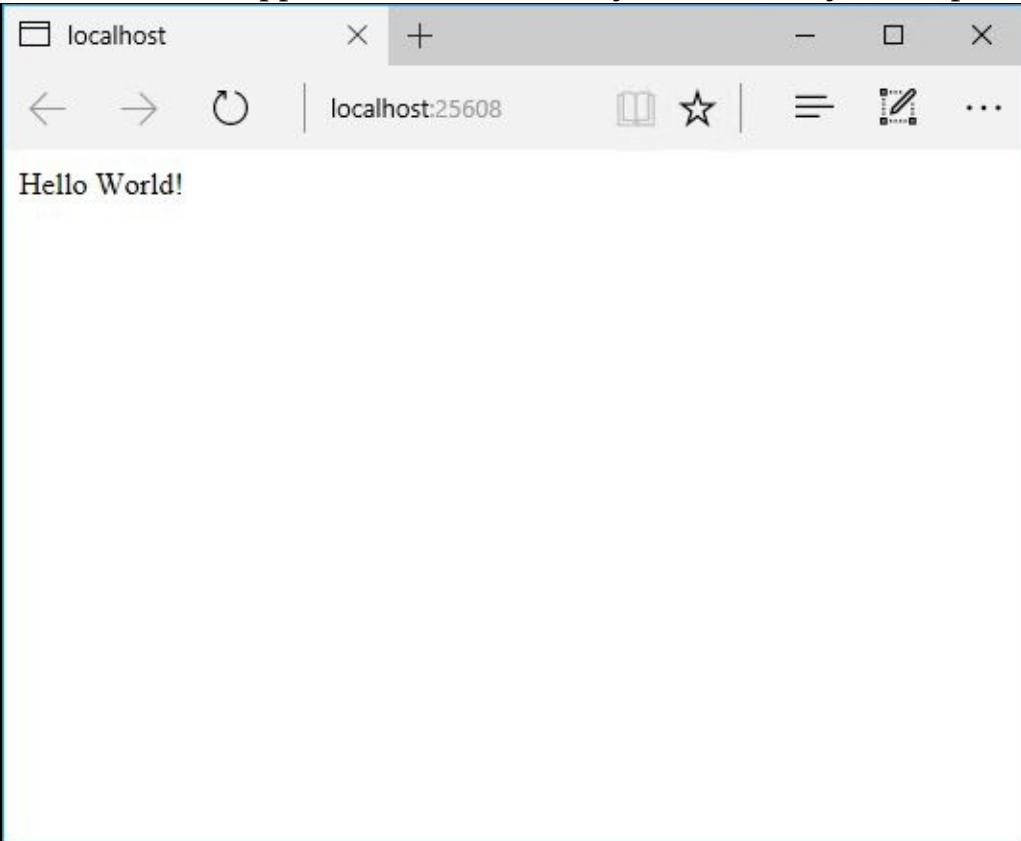

If you are running Visual Studio 2017 RC, what you need to do is click on Tools, NuGet Package Manager, Manage NuGet Packages for Solution... and see if there are any

updates to .NET Core. If you are on .NET Core 1.01, there should be an update to .NET Core 1.1 available via NuGet. Let NuGet update your project dependencies for you. After doing this, you must browse to <https://www.microsoft.com/net/download/core#/current> and make sure that you have selected the Current option under All downloads. Download the current .NET Core SDK installer for Windows and install it.

At this point, you can press *Ctrl + F5* to Start without Debugging and launch your ASP.NET Core application. This will start IIS Express, which is the default host for ASP.NET Core applications. The only thing it does now is to display the text Hello World!. You have successfully created and run an ASP.NET Core application. Don't close your browser yet. Keep it open:

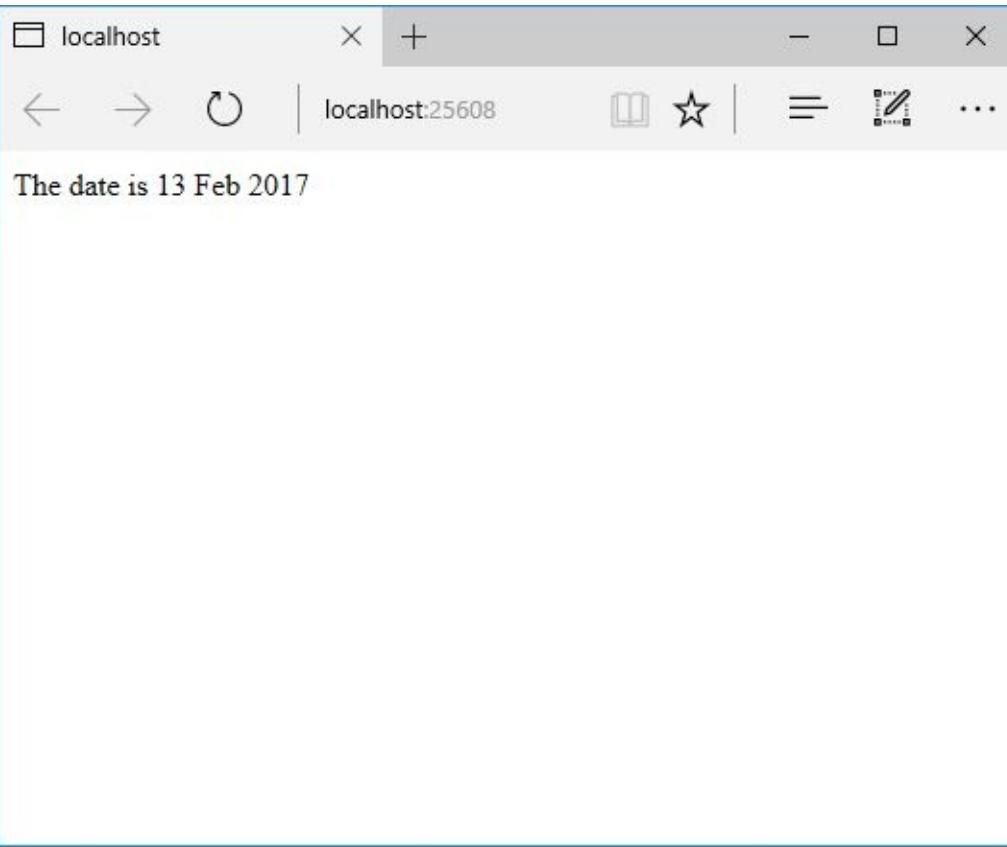

Note that the port number 25608 in the URL of the browser is a randomly selected port. The number you will see will most likely be different than in the book.

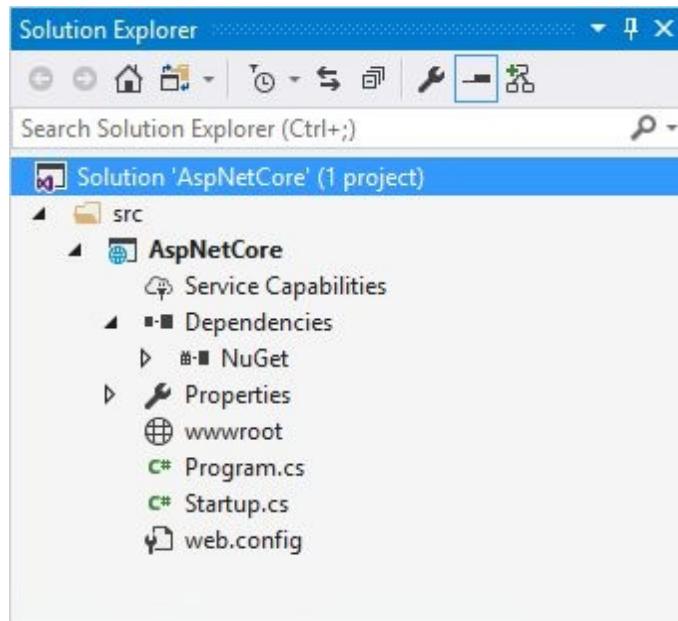

```
using System;  
using System.Collections.Generic;  
using System.Linq;  
using System.Threading.Tasks;  
using Microsoft.AspNetCore.Builder;  
using Microsoft.AspNetCore.Hosting;  
using Microsoft.Extensions.DependencyInjection;  
using Microsoft.Extensions.Logging;  
  
namespace AspNetCore  
{  
    public class Startup  
    {  
        // This method gets called by the runtime. Use this method to add services to the container.  
        // For more information on how to configure your application, visit  
        // https://go.microsoft.com/fwlink/?LinkID=398940  
        public void ConfigureServices(IServiceCollection services)  
        {  
            // This method gets called by the runtime. Use this method to configure the HTTP request pipeline.  
            public void Configure(IApplicationBuilder app, IHostingEnvironment env,  
ILoggerFactory loggerFactory)  
            {  
                loggerFactory.AddConsole();  
                if (env.IsDevelopment())  
                {  
                    app.UseDeveloperExceptionPage();  
                }  
                app.Run(async (context) =>  
                {  
                    await context.Response.WriteAsync("Hello World!");  
                });  
            }  
        }  
    }  
}
```

#### 4. Still in Notepad, edit the line that reads await

context.Response.WriteAsync("Hello World!"); and change it to read await context.Response.WriteAsync(\$"The date is {DateTime.Now.ToString("dd MMM yyyy")});. Save the file in Notepad and go to the browser and refresh it. You will see that the changes are displayed in the browser without me having to edit it in Visual Studio at all. This is because (as mentioned earlier) Visual Studio uses the file system to determine the project structure and ASP.NET Core detected the changes to the `Startup.cs` file and automatically recompiled it on the fly:

5. Looking at the Solution Explorer a little more in detail, I want to highlight some of the files in the project. The `wwwroot` folder will represent the root of the website when hosted. It is here that you will place static files such as images, JavaScript, and CSS style sheet files. Another file of interest is the `Startup.cs` file, which essentially replaces the `Global.asax` file. It is here in the `Startup.cs` file that you can write code to execute when your ASP.NET Core application starts up:

```
public static void Main(string[] args){<br/>    var host = new WebHostBuilder()<br/>        .UseKestrel()<br/>        .UseContentRoot(Directory.GetCurrentDirectory())<br/>        .UseIISIntegration()<br/>        .UseStartup<Startup>()<br/>        .Build();<br/><br/>    host.Run();<br/>}
```

Going back to our `Startup` class in the `Startup.cs` file, when you look inside this class you will see two methods. The methods are `Configure()` and `ConfigureServices()`. As you can see from the comment on the `Configure()` method, it is used *to configure the HTTP request pipeline*. Basically, incoming requests are handled by the application here and all it currently does in our application is to display the current date for every incoming request. The `ConfigureServices()` method is called before `Configure()` and is optional. Its explicit purpose is to add any services required by the application. ASP.NET Core supports dependency Injection natively. This means that if I can leverage services by injecting them into methods in the `Startup` class. For more information on DI, be sure to read <https://docs.microsoft.com/en-us/aspnet/core/fundamentals/dependency-injection>.

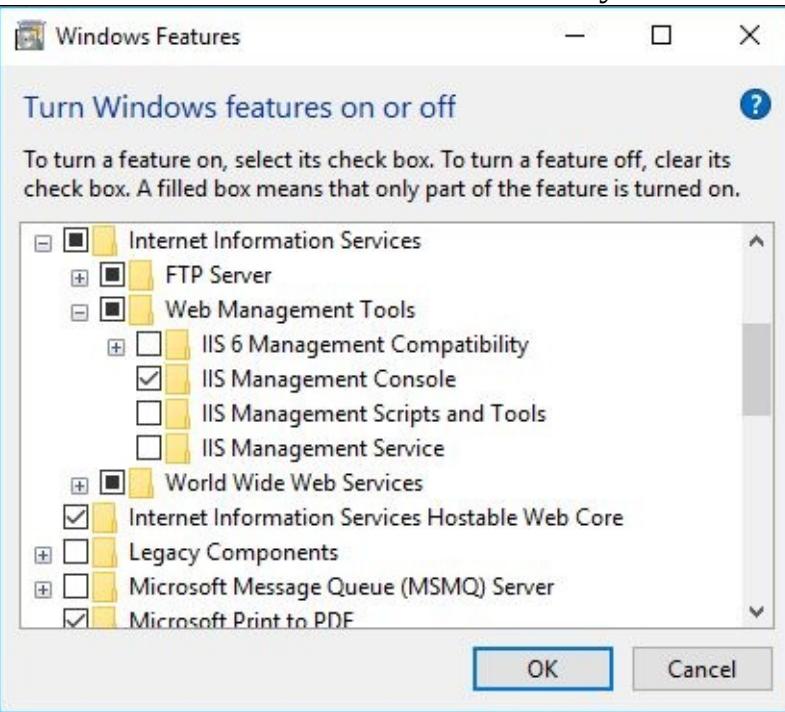

# **Publishing your ASP.NET Core application**

Publishing an ASP.NET Core application is quite straightforward. We will take a look at publishing the application via Command Prompt (run as administrator) and then publishing the ASP.NET Core application to IIS on a Windows server.

# Getting ready

You will need to have IIS set up in order to do this. Start Programs and Features and click on Turn Windows features on or off in the left-hand side of the Programs and Features form. Ensure that Internet Information Services is selected. When you select IIS, click OK to turn the feature on:

You also need to ensure that you have installed the .NET Core Windows Server Hosting bundle, which will create a reverse-proxy between IIS and the Kestrel server.

*At the time of this writing, the .NET Core Windows Server Hosting bundle is available at the following link:*

<https://docs.microsoft.com/en-us/aspnet/core/publishing/iis#install-the-net-core-windows-server-hosting-bundle>

The screenshot shows a Microsoft Edge browser window with the following details:

- Title Bar:** IIS Windows | Publishing to IIS | Micro
- Address Bar:** docs.microsoft.com/en-us/aspnet/
- Page Content:**
  1. Install the .NET Core Windows Server Hosting bundle on the server. The bundle will install the .NET Core Runtime, .NET Core Library, and the ASP.NET Core Module. The module creates the reverse-proxy between IIS and the Kestrel server.
  2. Restart the server or execute `net stop was /y` followed by `net start w3svc` from a command prompt to pick up a change to the system PATH.
- Note Callout:** If you only plan to host self-contained deployments and thus don't require the .NET Core runtime on the server, you have the option of only installing the ASP.NET Core Module by running the installer from an Administrator command prompt:  
`DotNetCore.1.1.0-WindowsHosting.exe OPT_INSTALL_LTS_REDIST=0  
OPT_INSTALL_FTS_REDIST=0`
- Note Callout:** If you use an IIS Shared Configuration, see [ASP.NET Core Module with IIS Shared](#)
- Feedback Button:** FEEDBACK

After installing the .NET Core Windows Server Hosting bundle, you need to restart IIS:

Open Command Prompt as administrator, type `iisreset` and press *Enter*. This will stop and then start IIS:

Administrator: Command Prompt

Microsoft Windows [Version 10.0.14393]  
(c) 2016 Microsoft Corporation. All rights reserved.

C:\Windows\system32>iisreset

Attempting stop...

Internet services successfully stopped

Attempting start...

Internet services successfully restarted

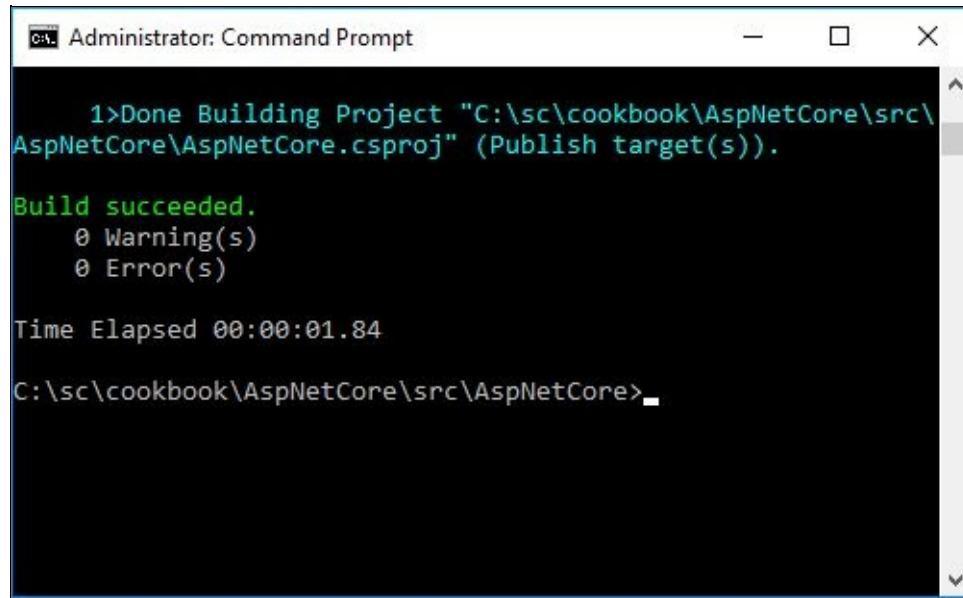

C:\Windows\system32>

# How to do it...

1. Open up Command Prompt by running it as administrator. In Command Prompt, go to the `src\AspNetCore` directory of your project. Ensure that you have a folder called `publish` in your `temp` folder on the `c:\` drive of your computer, then type in the following command, and press *Enter*. This will build and publish your project:

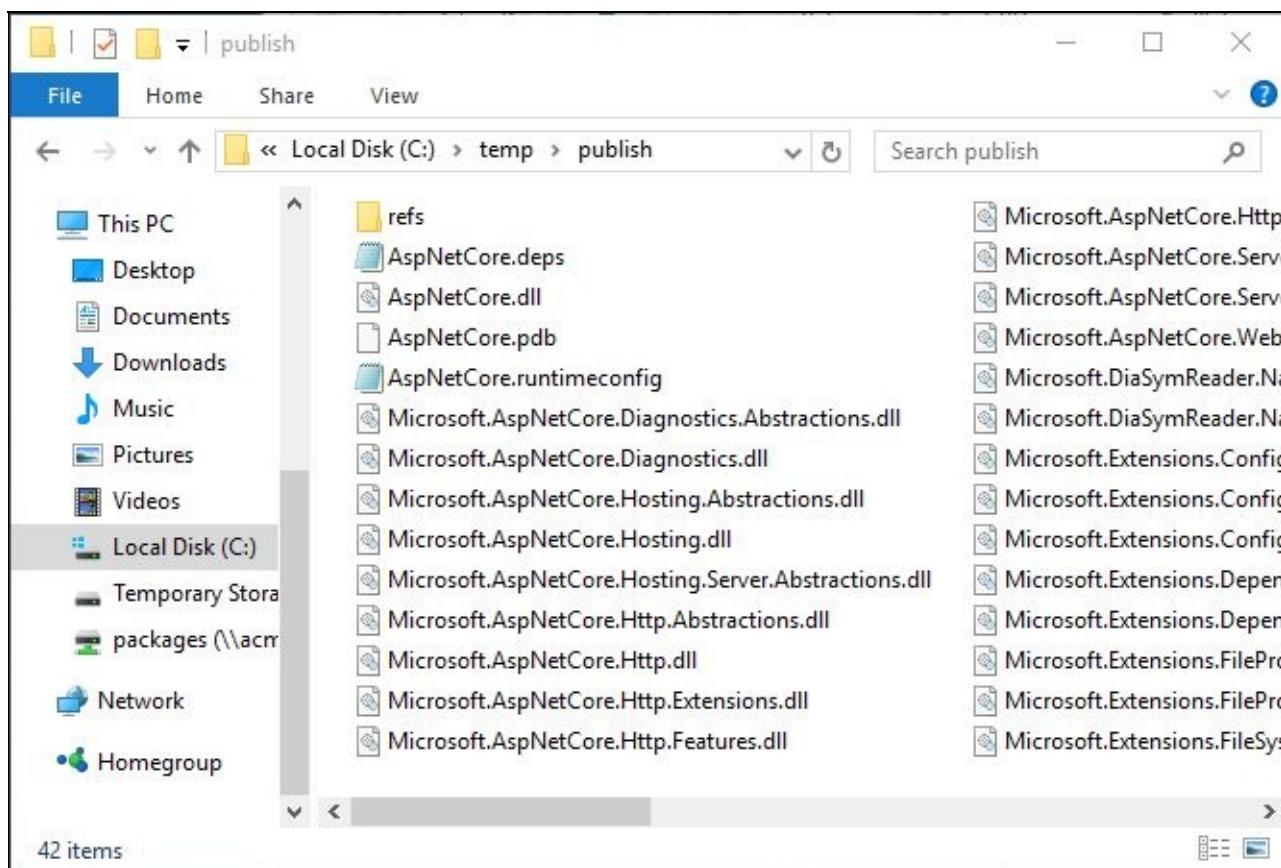

```
| dotnet publish --output "c:\temp\publish" --configuration release
```

The screenshot shows an 'Administrator: Command Prompt' window. The output of the command is displayed:  
1>Done Building Project "C:\sc\cookbook\AspNetCore\src\AspNetCore\AspNetCore.csproj" (Publish target(s)).  
Build succeeded.  
0 Warning(s)  
0 Error(s)  
Time Elapsed 00:00:01.84  
C:\sc\cookbook\AspNetCore\src\AspNetCore>

*Depending on what you called your ASP.NET Core application, the folder name under your `src` folder will be different to what mine is.*

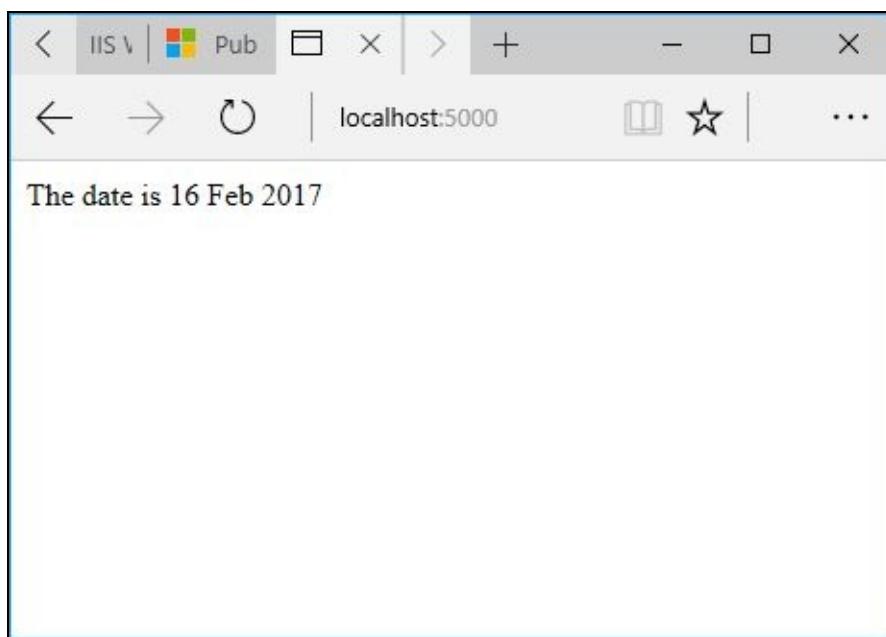

-  **TIP**
2. After the app has been published you will see the published files along with all their dependencies in the output folder:

3. Going back to Command Prompt, run the application by typing in `dotnet AspNetCore.dll`. Take note that if your ASP.NET Core application is called something else, the DLL you will run will be different from the example in the book.

A screenshot of an Administrator Command Prompt window. The title bar says 'Administrator: Command Prompt - dotnet AspNetCore.dll'. The command entered is 'dotnet AspNetCore.dll'. The output shows:  
C:\temp\publish>dotnet AspNetCore.dll  
Hosting environment: Production  
Content root path: C:\temp\publish  
Now listening on: http://localhost:5000  
Application started. Press Ctrl+C to shut down.  
The window has a dark background and white text.

You can now go to your browser and type in `http://localhost:5000`. This will display your ASP.NET

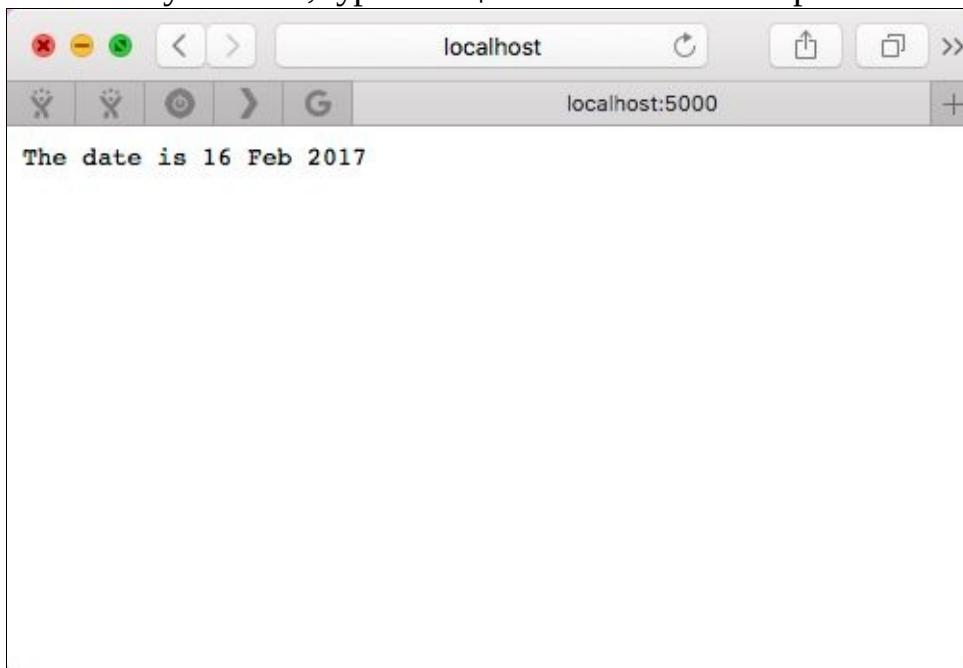

Core application for you:

4. You can do exactly the same on macOS by copying the published files to a folder and typing `dotnet AspNetCore.dll` in Terminal:

```
[nosferatu:publish dirkstrauss$ dotnet AspNetCore.dll
Hosting environment: Production
Content root path: /Users/dirkstrauss/Desktop/publish
Now listening on: http://localhost:5000
Application started. Press Ctrl+C to shut down.]
```

A screenshot of a macOS Terminal window titled 'publish — dotnet AspNetCore.dll — 80x7'. The window contains the command 'dotnet AspNetCore.dll' and its execution output. The output shows the hosting environment is Production, the content root path is '/Users/dirkstrauss/Desktop/publish', it is listening on 'http://localhost:5000', and the application has started. It also indicates that pressing Ctrl+C will shut down the application.

Then in Safari on your Mac, type in `http://localhost:5000` and press *Enter*. This will load the site in

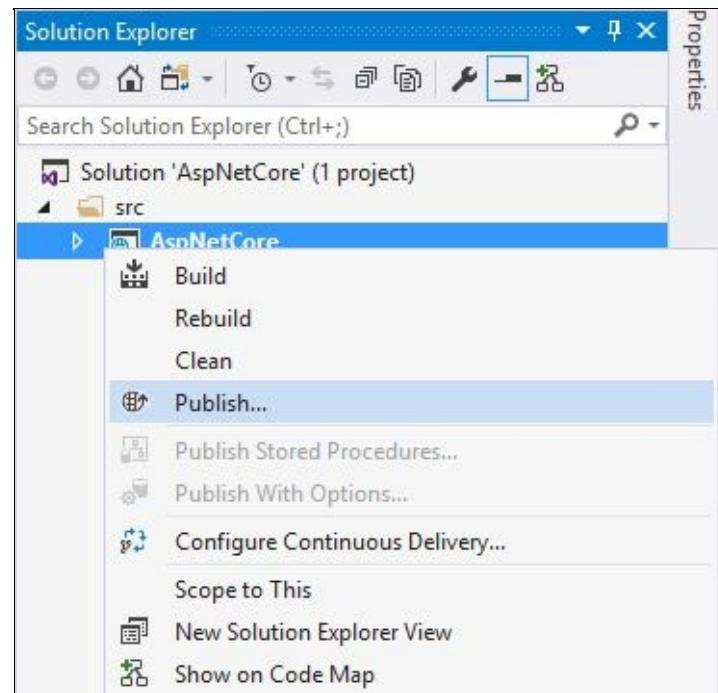

Safari:

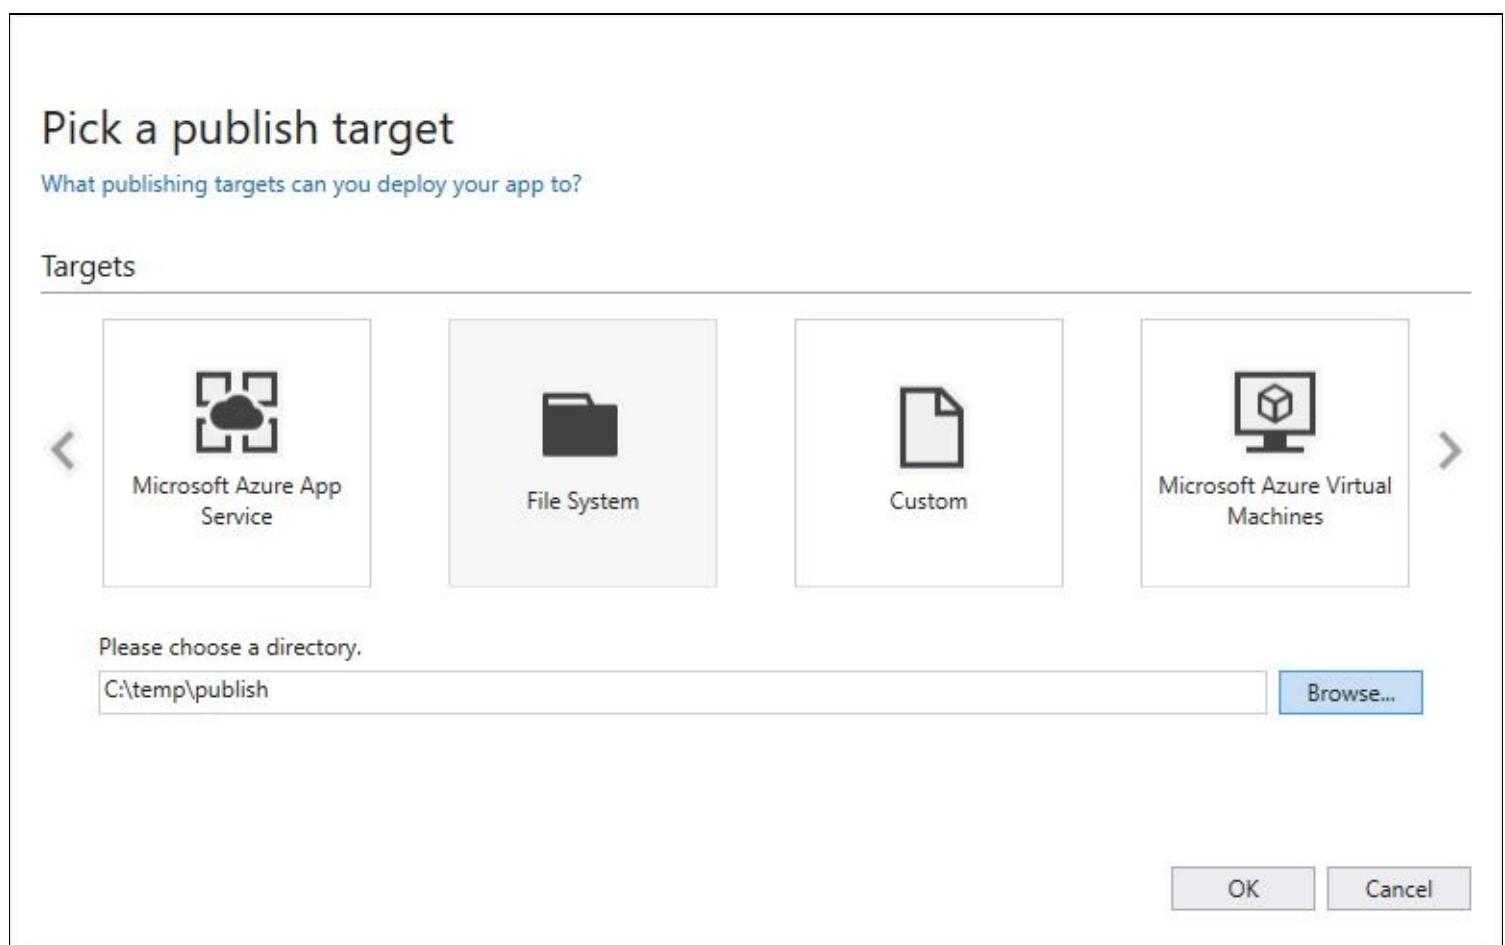

While I have just shown Safari running on macOS as an alternative, the ASP.NET Core application run happily on Linux too.

5. Publishing the application to IIS is also easily done. In Visual Studio, right-click on the project in the

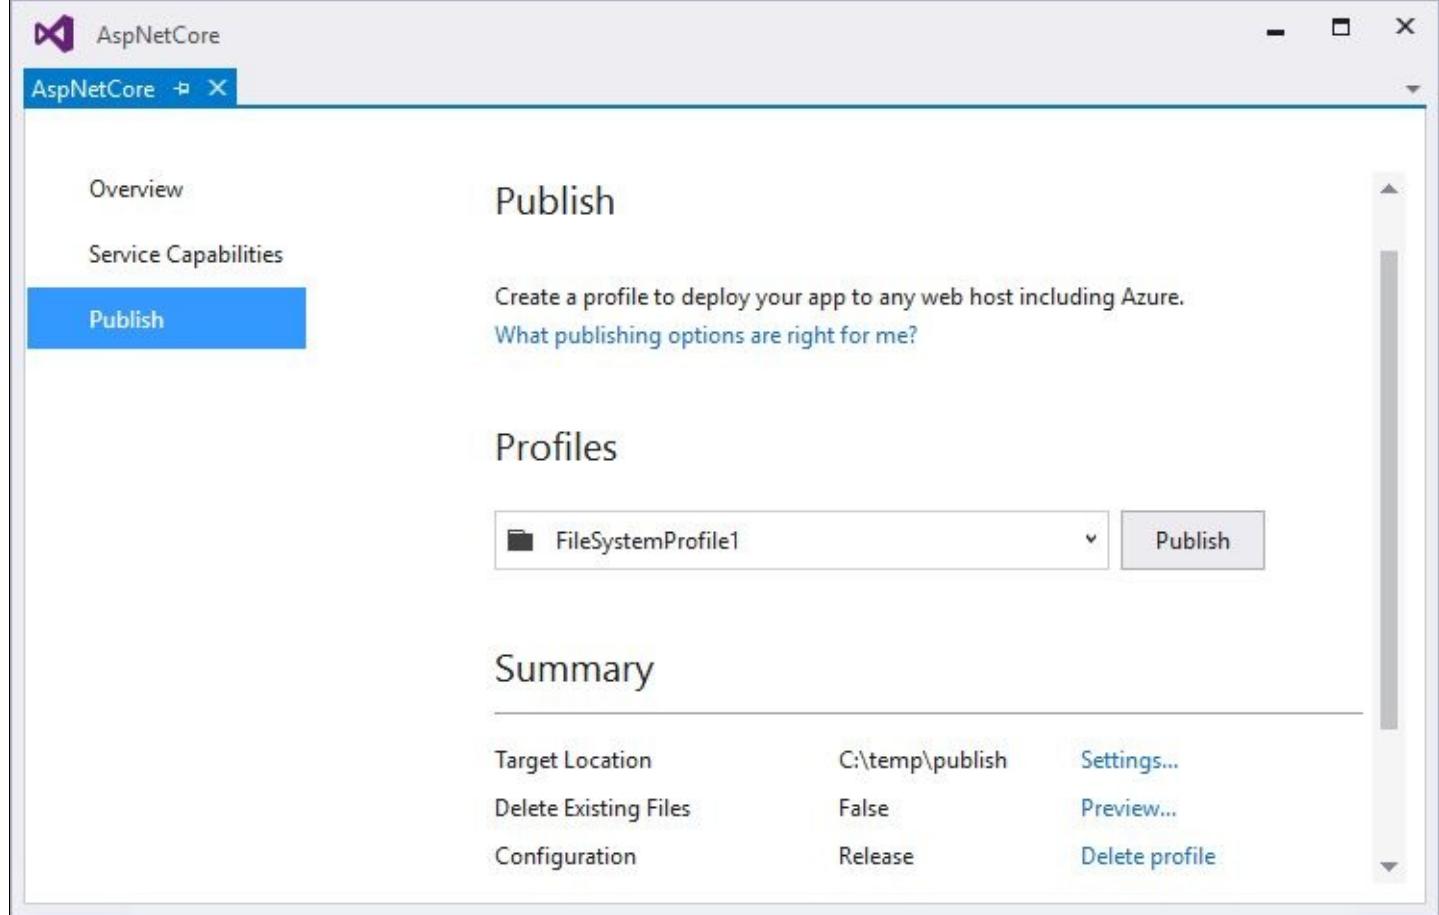

Solution Explorer and click on Publish... from the context menu:

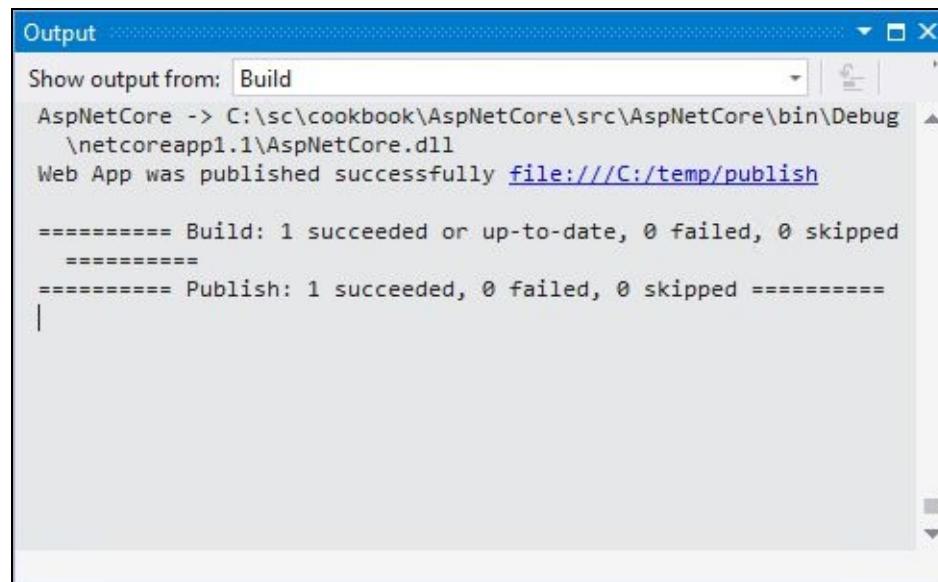

6. You then need to select a publish target. There are a few options available to you, but for this example, you need to select the File System option and click on OK:

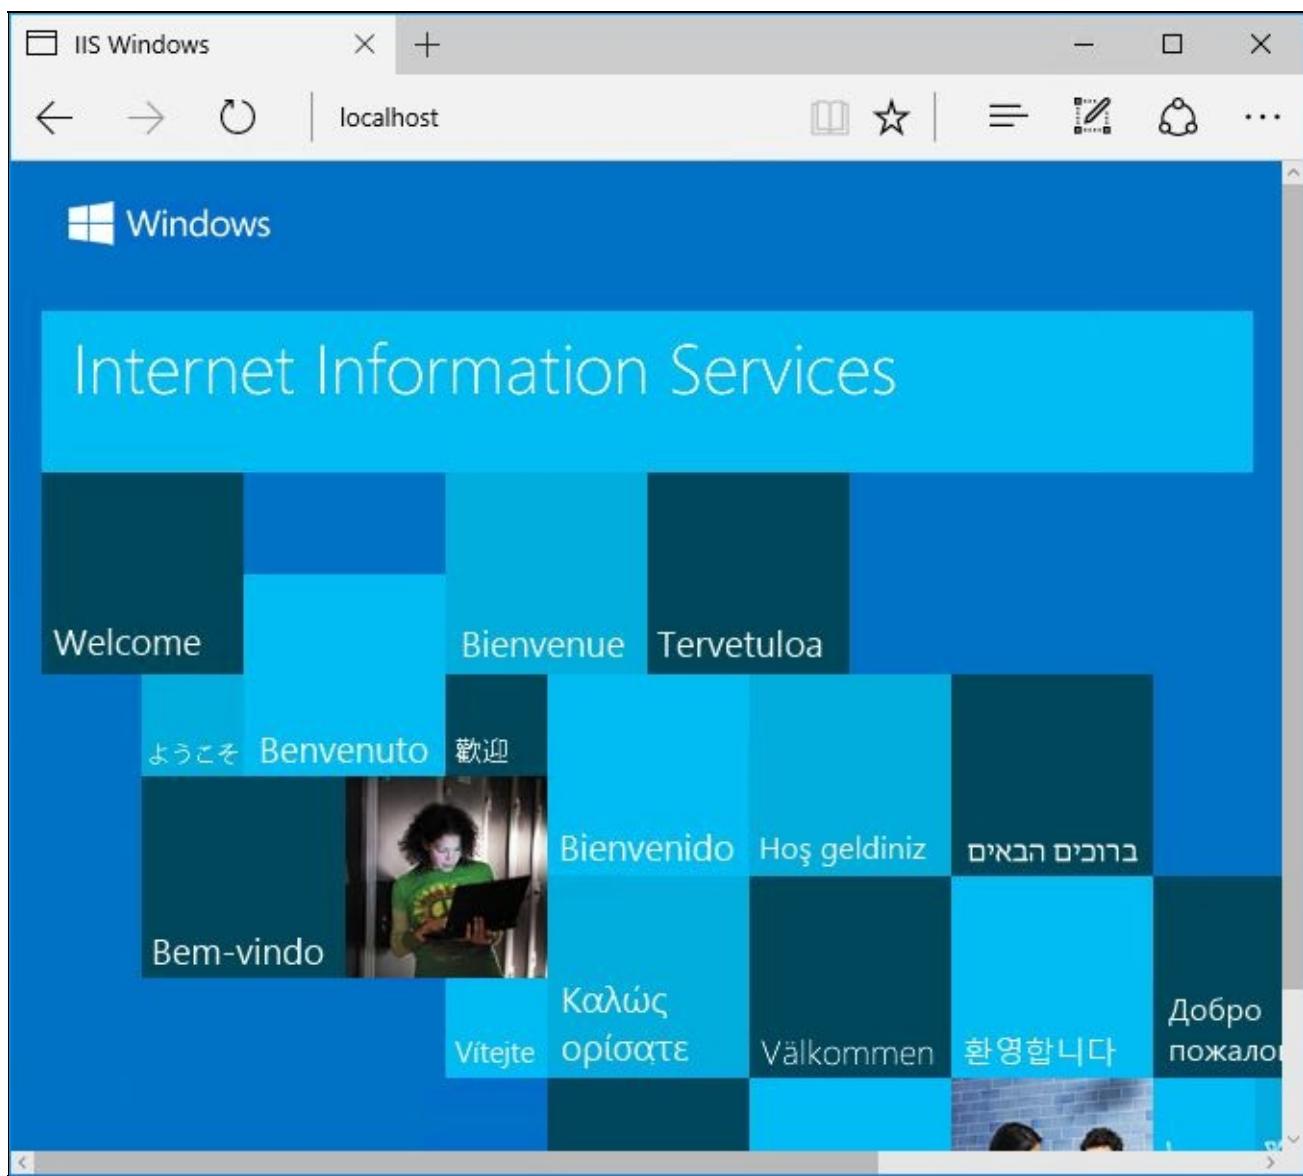

7. Back in the publish screen you can modify additional settings by clicking on Settings... next to the Target Location path. Here you need to select the publishing to be done in Release mode. Finally, click on the Publish button.

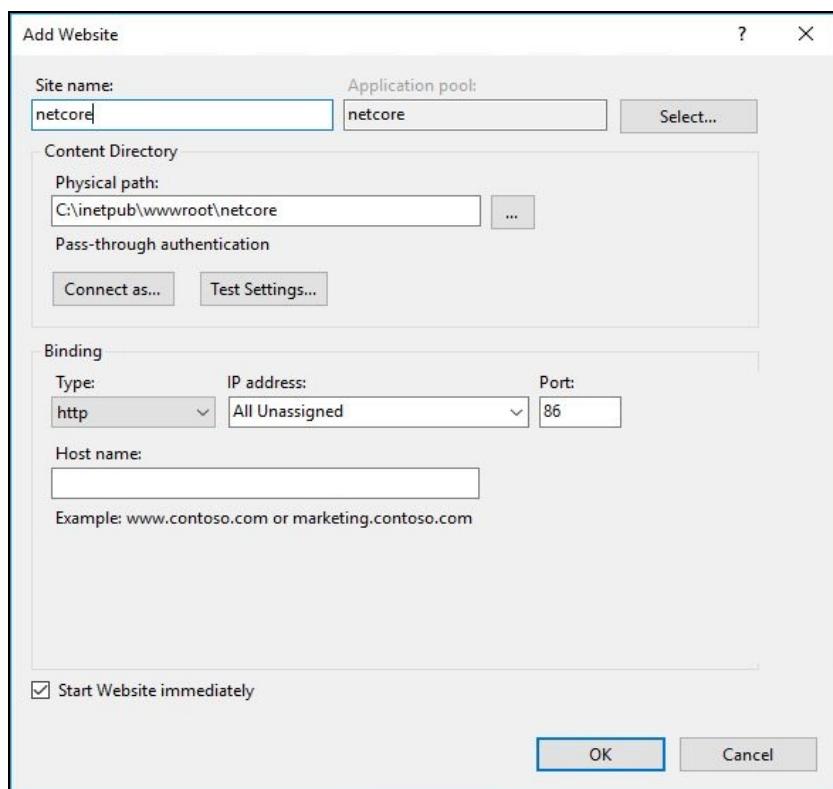

- When the app has been published, Visual Studio will display the results in the Output window along with the publish location you selected:

- In your browser, if you enter `http://localhost` you will see the default page for IIS. This means that IIS is set up:

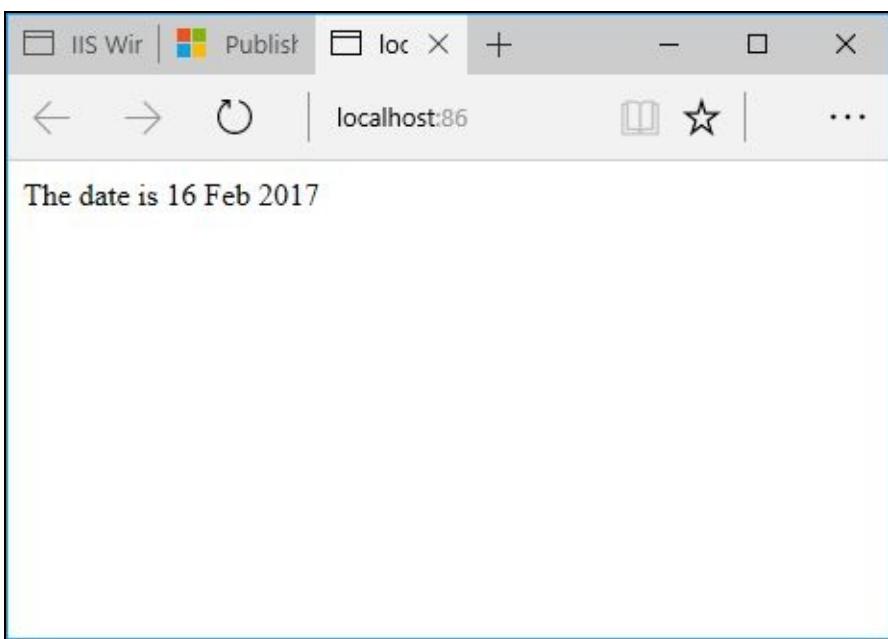

10. In Windows Explorer, browse to `C:\inetpub\wwwroot` and create a new folder called `netcore`. Copy the published files from your ASP.NET Core application into this new folder you created. In IIS, add a new website by right-clicking on the `sites` folder and selecting Add Website. Give the site a name and select the path you copied the published files to in the Physical path setting. Lastly, change the Port to `86` as port `80` is used by the default website and click on OK:

11. You will see your website added to the Sites folder in IIS. Under the Browse Website heading in the right-hand panel of IIS Manager, click on Browse \*:86 (http):

15. This will launch your ASP.NET Core application inside your default browser:

# How it works...

Creating an ASP.NET Core application on Windows allows us to run the application on Windows, as well as macOS and Linux. Running it standalone is done easily via the `dotnet` command in Windows Command Prompt or in Terminal on macOS. This is what makes .NET Core so powerful for the future of application development. You can use the IDE you are used to in order to develop applications that are platform independent. There is a lot more to know surrounding .NET Core and you would really need to dig in to understand the concept and learn what it is capable of.

# ASP.NET Core on the MVC Framework

This chapter will explore creating an ASP.NET Core application with the MVC framework. The previous chapter introduced you to ASP.NET Core, and we started with the basics needed for this chapter. If you are not familiar with ASP.NET Core, take a look at what [Chapter 10, Exploring .NET Core 1.1](#) has to offer. We will be looking at:

- Including middleware and why it is useful
- Creating Controllers and using routing
- Rendering Views

# Introduction

The MVC framework is named according to the MVC design pattern it follows. MVC stands for **Model-View-Controller**. An HTTP request is sent to a Controller, which is then mapped to a method inside the *Controller* class. Inside that method, the Controller decides what to do with the HTTP request. It then constructs a *model* that is agnostic to the Controller and request. The model brings all the logic together that contains the information the Controller needs. The *view* is then used to display the information contained inside the model to build an HTML page that gets sent back to the requesting client in the HTTP response.

What the MVC framework allows us to do is separate the logic by letting each component of the framework focus on one specific thing:

- The Controller receives the HTTP request and builds a model
- The model contains the data we requested and sends it to the view
- The view then creates the HTML page from the data contained in the model

# Including middleware and why it is useful

This recipe will show you how to set up middleware in your ASP.NET Core application. Middleware in ASP.NET defines how our application responds to any HTTP requests it receives. It is also useful for controlling how our application responds to user authentication or errors. It can also perform logging operations regarding incoming request.

# Getting ready

We need to modify the code contained inside the `Configure()` method of our `Startup` class. It is here that we set up middleware in an ASP.NET Core application. In [Chapter 10, Exploring .NET Core 1.1](#), we saw that our `Configure()` method already contained two pieces of middleware. The first is a piece of middleware that will display a developer exception page when an unhandled exception is caught. The code looks as follows:

```
{  
    app.UseDeveloperExceptionPage();  
}
```

This will display any error messages which is useful for debugging the application. Typically, this page would contain information such as a stack trace. It is only installed when the application is in development mode. When you first create an ASP.NET Core application, it is in development mode.

The second middleware is the `app.Run()` and will always be present in your application. In [Chapter 10, Exploring .NET Core 1.1](#), it would always respond with the current date. Think of middleware as gate keepers. All HTTP requests coming in to your application must pass through your middleware.

It is also important to know that the order you add your middleware is important. In the `app.Run()` middleware, we did a `context.Response.WriteAsync()`. Any middleware added after this will not be reached because the processing pipeline terminates in `app.Run()`. This will become clearer as we move on.

```
public void Configure(IApplicationBuilder app, <br/> IHostingEnvironment env, <br/>
ILoggerFactory loggerFactory)<br/> {<br/> loggerFactory.AddConsole();<br/><br/> if
(env.IsDevelopment())<br/> {<br/> app.UseDeveloperExceptionPage();<br/> }<br/>
<br/> app.Run(async (context) =><br/> {<br/> await
context.Response.WriteAsync($"The date is <br/> {DateTime.Now.ToString("dd MMM
yyyy")}" );<br/> });<br/> }

if (env.IsDevelopment())<br/> {<br/> app.UseDeveloperExceptionPage();<br/> }<br/>
<br/> app.UseWelcomePage();<br/><br/> app.Run(async (context) =><br/> {<br/> await
context.Response.WriteAsync($"The date is <br/> {DateTime.Now.ToString("dd MMM
yyyy")}" ); <br/> });

app.UseWelcomePage("/hello");

app.Run(async (context) =><br/> {<br/> throw new Exception("Error in app.Run()");<br/>
await context.Response.WriteAsync($"The date is <br/>
{DateTime.Now.ToString("dd MMM yyyy")}" ); <br/> });

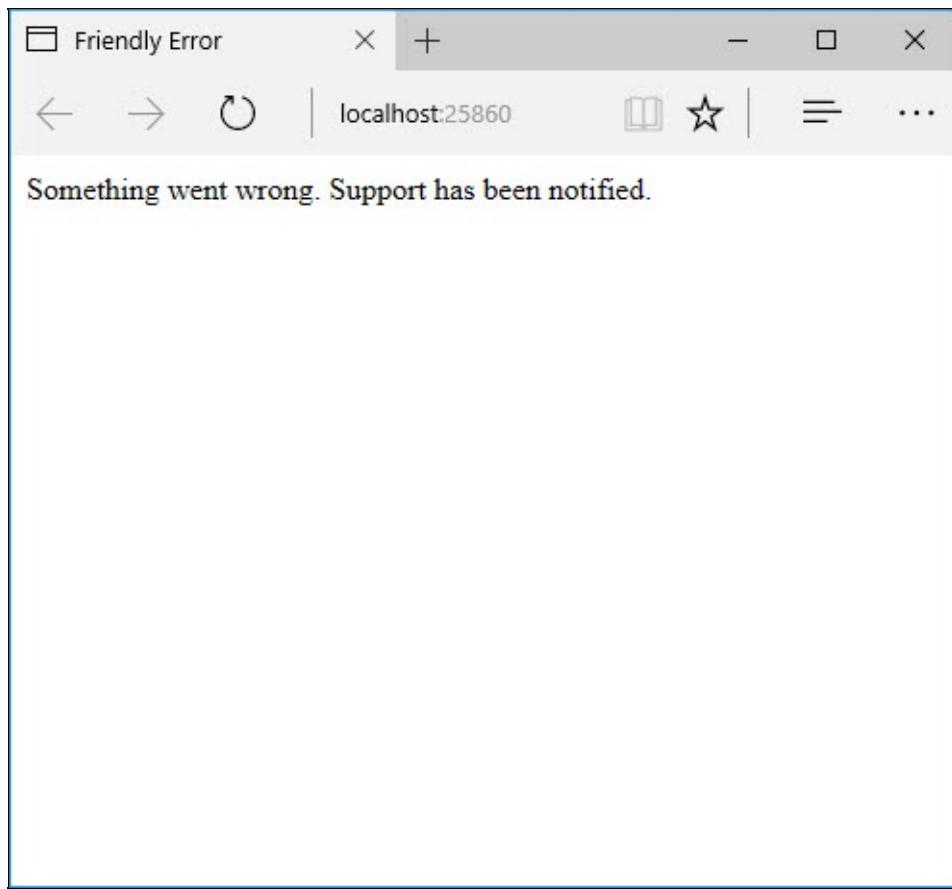

<!DOCTYPE html><br/> <html><br/> <head><br/> <meta charset="utf-8" /><br/>
<title>Friendly Error</title><br/> </head><br/> <body><br/> Something went wrong.
Support has been notified.<br/> </body><br/> </html>

env.EnvironmentName = EnvironmentName.Production;<br/> if (env.IsDevelopment())
<br/> {<br/> app.UseDeveloperExceptionPage();<br/> }<br/> else<br/> {<br/>
DefaultFilesOptions options = new DefaultFilesOptions();<br/>
options.DefaultFileNames.Add("friendlyError.html");<br/> app.UseDefaultFiles(options);
<br/><br/> app.UseExceptionHandler("/friendlyError"); <br/> }<br/><br/>
app.UseStaticFiles();
```

# How it works...

Press *Ctrl + F5* again to restart IIS Express and launch our application. You will see that our custom error page has been displayed inside the browser:

In reality, we will probably use a controller to do this kind of thing. What I wanted to illustrate here was the use of adding a custom default page and to display that page when an exception happens in the production environment.

As you can see, middleware in ASP.NET Core is really useful. There is a lot of documentation regarding this topic, and I encourage you to do some further reading on the topic. Start with the Microsoft documentation at <https://docs.microsoft.com/en-us/aspnet/core/fundamentals/middleware>.

# **Creating Controllers and using routing**

Inside the MVC framework, the Controllers, Models, and Views need to work together to form the HTTP request and response cycle. The fundamental starting point, however, is calling the correct Controller based on the HTTP request it receives. Without that, our application built on the MVC framework can't work. In the MVC framework, the process of calling the correct Controller for the HTTP request is known as routing.

# Getting ready

We can route HTTP requests to the correct Controllers by looking at what routing information is contained in the middleware of our application. The middleware then uses this routing information to see if the HTTP request needs to get sent to a Controller or not. Middleware will have a look at the incoming URL and match that up with the configuration information we provide it with. We can define this routing information in the `Startup` class using one of two routing approaches, namely:

- Convention-based routing
- Attribute-based routing

This recipe will explore these routing approaches. Before we can do that, we need to add the ASP.NET MVC NuGet package to our application. You should be rather familiar with adding NuGet packages to your application by now. Inside the NuGet Package Manager, browse for and install the `Microsoft.AspNetCore.Mvc` NuGet package. This will expose new middleware for our application, one of which is `app.UseMvc()`. This is used to map an HTTP request to a method in one of our Controllers. Modify the code in your `Configure()` method as follows: `loggerFactory.AddConsole()`:

```
if (env.IsDevelopment())
{
    app.UseDeveloperExceptionPage();
}
else
{
    DefaultFilesOptions options = new DefaultFilesOptions();
    options.DefaultFileNames.Add("friendlyError.html");
    app.UseDefaultFiles(options);

    app.UseExceptionHandler("/friendlyError");
}

app.UseStaticFiles();
app.UseMvc();
```

Next, we need to register our MVC services that the MVC framework requires in order to function. Inside `ConfigureServices()` add the following:

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddMvc();
}
```

After this is complete, we have the basics set up for MVC to function.

```

public class StudentController<br/> {<br/> public string Find()<br/> {<br/> return
"Found students";<br/> }<br/> }

private void FindController(IRouteBuilder route)<br/> {<br/><br/> }

private void FindController(IRouteBuilder route)<br/> {<br/> route.MapRoute("Default",
"{controller}/{action}");<br/> }

public void ConfigureServices(IServiceCollection services)<br/> {<br/>
services.AddMvc();<br/> }<br/><br/> public void Configure(IApplicationBuilder app,
<br/> IHostingEnvironment env, ILoggerFactory loggerFactory)<br/> {<br/>
loggerFactory.AddConsole();<br/><br/> if (env.IsDevelopment())<br/> {<br/>
app.UseDeveloperExceptionPage();<br/> }<br/> else<br/> {<br/> DefaultFilesOptions
options = new DefaultFilesOptions();<br/>
options.DefaultFileNames.Add("friendlyError.html");<br/> app.UseDefaultFiles(options);
<br/><br/> app.UseExceptionHandler("/friendlyError"); <br/> }<br/><br/>
app.UseStaticFiles();<br/> app.UseMvc(FindController);<br/> }<br/><br/> private void
FindController(IRouteBuilder route)<br/> {<br/> route.MapRoute("Default", "
{controller}/{action}");<br/> }

public class ErrorController<br/> {<br/> public string Support()<br/> {<br/> return
"Content not found. Contact Support";<br/> }<br/> }

route.MapRoute("Default", "{controller=Error}/{action=Support}");

[Route("Error")]<br/> public class ErrorController<br/> {<br/> [Route("Support")]<br/>
public string Support()<br/> {<br/> return "Content not found. Contact Support";<br/> }
<br/> }

```

13. In the startup class inside the `FindController()` method, comment out the line `route.MapRoute("Default", "{controller=Error}/{action=Support}");`. In the browser, add the text `/Error/Support` to the end of your URL and enter. You will see that the application correctly matches the `ErrorController`, based on the attributes defined inside the `ErrorController` class.

# How it works...

Routing inside the MVC framework is a very flexible method of accessing specific Controllers, based on HTTP requests. If you need more control over the Controller that is accessed, attribute-based routing would probably be a better fit than convention-based routing. That said, there are additional things you can do when using attribute-based routing. Take a look at what is available to you as a developer when using attribute-based routing.

# Rendering Views

So far we have been using plain C# classes as Controllers, but it is far more common have your Controllers inherit from the `Controller` base class which the MVC framework provides. This allows developers to return complex objects from their Controllers, students in our case. These complex return types are returned in a result that implements the `IActionResult` interface. We can, therefore, return JSON, XML, and even HTML to return to the client. The usage of this and creating Views is what we will be looking at next in this recipe.

# Getting ready

Open up the `StudentController` class and modify it to contain attribute-based routing. Be sure to add the `using Microsoft.AspNetCore.Mvc;` namespace to the `StudentController` class. Also, inherit from the `Controller` base class.

```
[Route("Student")]
public class StudentController : Controller
{
    [Route("Find")]
    public string Find()
    {
        return "Found students";
    }
}
```

Then, add another folder to your project called `Models`. Inside the `Models` folder, add a class called `Student` because our application will be returning student information. This will be a simple class with properties for the student number, first name, and last name. Your `Student` class should look as follows:

```
public class Student
{
    public int StudentNumber { get; set; }
    public string FirstName { get; set; }
    public string LastName { get; set; }
}
```

Back in the `StudentController`, we want to instantiate our `Student` model and give it some data. We then change the return type of the `Find()` method from `string` to `IActionResult`. Also, add the `using AspNetCore.Models;` namespace to your `StudentController` class.

*Note, if your project is called something other than `AspNetCore`, your namespace will change accordingly:  
using [projectname].Models;*

Your code should now look as follows:

```
[Route("Find")]
public IActionResult Find()
{
    var studentModel = new Student
    {
        StudentNumber = 123
        , FirstName = "Dirk"
        , LastName = 'Strauss'
    };
    return View(studentModel);
}
```

Ultimately, we want to return a view result from our `StudentController`. We now have everything set up to do that next.

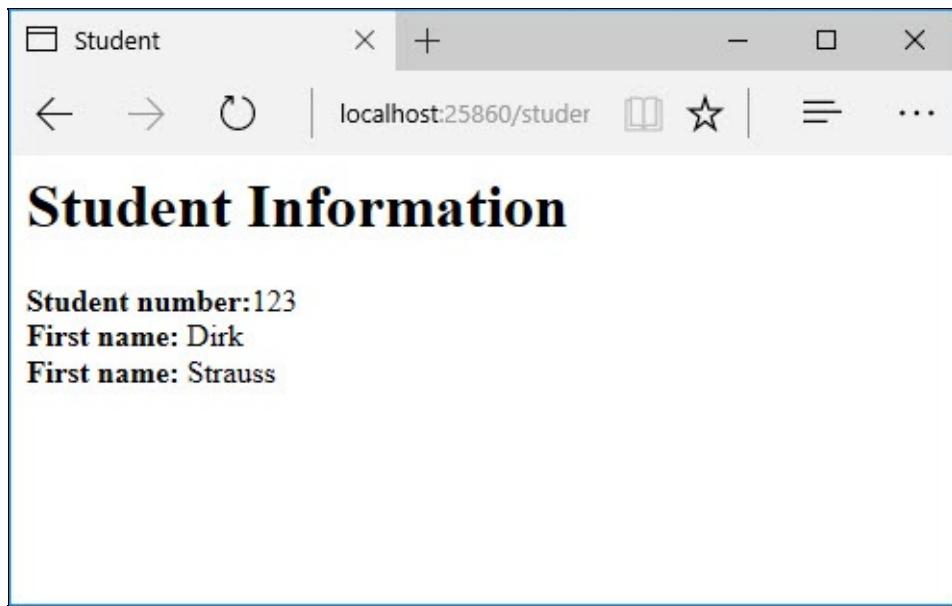

```
<html xmlns="http://www.w3.org/1999/xhtml"><br/> <head><br/> <title></title><br/>
</head><br/> <body><br/> </body><br/> </html>

@model AspNetCore.Models.Student<br/> <html
xmlns="http://www.w3.org/1999/xhtml"><br/> <head><br/> <title>Student</title><br/>
</head><br/> <body><br/> <div><br/> <h1>Student Information</h1><br/>
<strong>Student number:</strong>@Model.StudentNumber<br /><br/> <strong>First
name: </strong>@Model.FirstName<br /><br/> <strong>First name:
</strong>@Model.LastName<br /><br/> </div><br/> </body><br/> </html>
```

# How it works...

Save your code and refresh your browser. Your URL should be [http://localhost:\[your port number\]/student/find](http://localhost:[your port number]/student/find) for this to work correctly.

The HTTP request is routed to the `StudentController` that in turn populates and returns the `student` model containing the data we need and sends it to the Find Razor view. This is the essence of what the MVC framework is all about. There is a lot more to cover when it comes to the MVC framework and ASP.NET Core, but this chapter just deals with the basic introduction to these topics.

TIP

*We as developers are continually challenged to stay up to date with the latest and greatest technologies. There is a drive in us to learn more and become better at what we do. The very fact that you are reading this book is a testament to that. Regarding this chapter, however, .NET Core and the MVC framework are areas that definitely need more learning. It is not possible to cover all there is to know in a single chapter. There are various online resources available to developers. I find that one of the best (and free) resources for learning new tech is the Microsoft Virtual Academy at <https://mva.microsoft.com>. Free Microsoft training is delivered by experts.*

Hopefully, this is enough to pique your interest and will encourage you to research the topics further.

# Choosing and Using a Source Control Strategy

Source control is an essential part of every developer's toolkit. It doesn't matter whether you are a hobbyist or professional programmer, when you get up from your desk to go home, you better be sure your code is safe. In this chapter, we will be looking at choosing and using a source control strategy. Some of the topics we will be taking a look at are:

- Setting up Visual Studio account management and determining which source control solution is best for you
- Setting up Visual Studio GitHub integration, checking in code for the first time, and checking in changes
- Working as a team using GitHub, handling and resolving conflicts in code

# Introduction

During my career, I used Visual SourceSafe, SVN, VSTS, Bitbucket, and GitHub. It really does not matter how you approach it, the important thing is that you keep your source code safe and versioned. When I first started working with source control, the company I worked at used Visual SourceSafe. If you are unfamiliar with the software, just Google it. You will see results come back containing words such as hate, unpleasant, bad, and Microsoft's source destruction system. You get the point.

We had an employee leave files exclusively checked out to him, after he resigned and emigrated to another country. I'm beginning to wonder if the company policy to enforce the use of SourceSafe wasn't the reason he emigrated. But jokes apart, it gave us endless problems. Slap SourceSafe on a large project, and you could end up with a disaster. These days, however, developers have excellent choices available to them.

The two that stand out are obviously Microsoft Team Services and GitHub. Both have a free tier, but the decision of using one over the other depends entirely on your unique situation.

# **Setting up Visual Studio account management and determining which source control solution is best for you**

Visual Studio allows developers to create an account and sign in. This is particularly beneficial if you hot desk often or work in multiple locations on different machines (think work and home PCs), because Visual Studio will then automatically sync your settings between the machines you're signed in to.

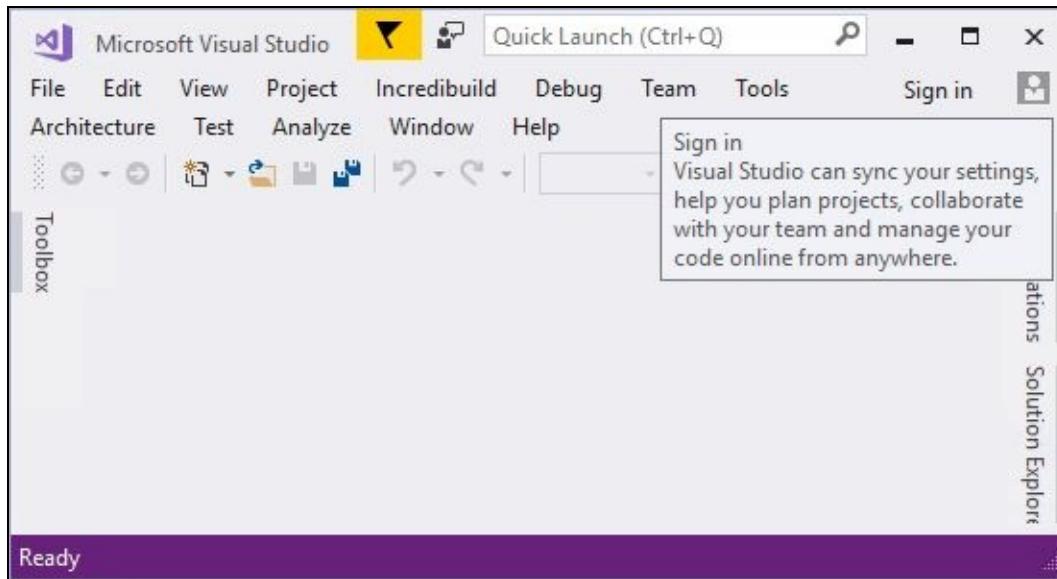

# Getting ready

This recipe will assume that you have just completed installing Visual Studio 2017 on your machine. It doesn't matter whether you have installed the trial or licensed version of Visual Studio 2017.

# How to do it...

1. After installation completes, open up Visual Studio.
2. At the top right of Visual Studio, you will see that there is a Sign in link:

3. Clicking on the Sign in link, you will be allowed to enter your e-mail address here. I find it useful to just use my Outlook e-mail address. In my opinion, it is one of the best web e-mails available.

*Note that I'm not endorsing Outlook for any other reason other than I really think it is a great product. I also have a Gmail account as well as an iCloud e-mail account.*

4. After adding your e-mail account, Visual Studio will redirect you to a sign in page.
5. Because I already have an Outlook account, Visual Studio simply allows me to sign in with it. If, however, you need to create an account, you can do so from the sign up link on the Sign in to Visual Studio form:

## Sign in to Visual Studio

Visual Studio will help you plan projects, collaborate with your team, and manage your code online from anywhere.

[Learn more](#)

Sign in to start using your Azure credits, publish code to a private Git repository, sync your settings, and unlock the IDE.

6. Visual Studio will now redirect you to a sign up page where you can go and create an account:

- After your account is created, you will be prompted to return to Visual Studio to sign in. After you have signed in, Visual Studio will display your details in the right-hand corner of the IDE:

- Clicking on the down arrow next to your account name, you can view your Account settings....

9. This will show you a summary of your account, from where you can further personalize your account:

The screenshot shows the 'Personalization Account' dialog in Visual Studio. It displays the account information: 'dirk\_developer' and 'dirk\_developer@outlook.com'. There are links to 'Manage Visual Studio profile' and 'Sign out'. A note states: 'Your personalization account is used to roam settings across devices, and to provide other personalized services.' To the right, it shows the 'Visual Studio' section for 'Enterprise 2017', indicating a 'License: MSDN Subscription' and 'This product is licensed to: dirk\_developer@outlook.com'. It also has links to 'Check for an updated license' and 'Unlock with a Product Key'. At the bottom, the 'All Accounts' section lists a 'Microsoft account' with the same details, and a 'Remove' link. A 'Close' button is visible in the bottom right corner.

# How it works...

The choice of source control is a topic every developer has a strong opinion about. Unfortunately, if you work for a boss, that decision might not even be up to you. Many companies have already set up their source control system just the way they like it, and you will need to fall in with company procedure. That is just the way it is. It is, however, good to know about the options available to you as an indie developer.

All good developers should be writing code in their own time too. You are not only a developer while you sit at work. We eat, breathe, sleep, and live code. It is part of who and what we are. I will say that in order for you to become better at your job as a developer, you must play with code in your own time. Start a pet project, get some friends together, and decide to write some software together. Not only will this make you all better at what you do, but you will learn a lot from each other.

If you are a remote developer who does not commute to and work in an office every day, you can still connect with the developer community. There are so many resources available to developers, and the developer community is more than happy to rally around newbies and help them grow. Starting a solo or pet project is useless if you don't commit (pun intended) to keeping your code safe. To do this, you don't have to pay a single dollar either. **Visual Studio Online** (now called **Team Services**) and GitHub provide developers with a fantastic platform to keep your code safe.

Let's start by looking at Team Services. The site can be found by pointing your browser to <https://www.visualstudio.com/team-services/>.

Here you will see that Microsoft has given developers a fantastic opportunity to use Team Services. It is absolutely free for up to five users. This means that you and your mates can collaboratively work on the next big thing while ensuring that your code remains secure. Signing up is as simple as clicking on the Get started for free link:

*For information on pricing, visit the following link:*  
<https://www.visualstudio.com/team-services/pricing/>

The second excellent option is GitHub. It differs slightly in its free offering by requiring developers to use a public repository on the free account. If you don't mind your code being essentially open source, then GitHub is a great choice. With GitHub though, you can have unlimited collaborators and public repositories:

*For information on pricing, visit the following link:*  
<https://github.com/pricing>

The choice of source control essentially comes down to the openness of your code. If you can afford to let other developers see and download your code, then GitHub is a great choice. If you need your code to remain private and only shared between specific people, then a paid GitHub account will suit you better. If you don't want to fork out money yet, then Team Services will be your best bet.

# **Setting up Visual Studio GitHub integration, checking in code for the first time, and checking in changes**

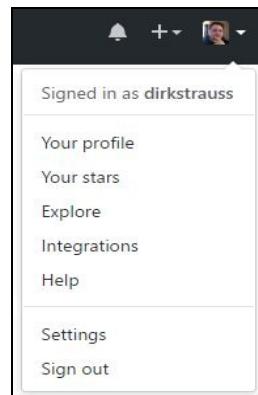

GitHub has been a tour de force for so many years. There are developers that swear by it. In fact, it is the default option when using Apple's Xcode IDE. For whatever reason you decide to use GitHub, rest assured that you and your code are in good hands.

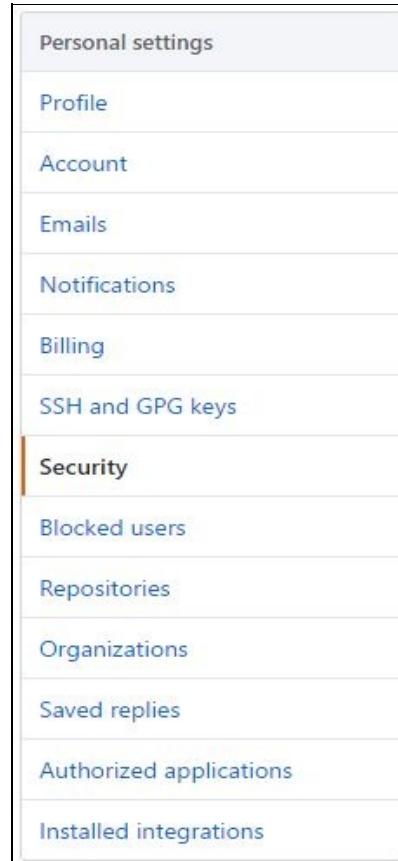

# Getting ready

The following recipe will assume that you have already signed up for GitHub and that you have enabled Two-factor authentication. If you have not signed up for a GitHub account, you can do so by going to <https://github.com/> and creating a new account. To enable Two-factor authentication on your GitHub account (something I personally strongly advise), do the following:

1. Click on the down arrow next to your profile image, and select Settings:

2. From the Personal settings menu that appears on the left of the next web page, select Security:

3. The first section on the security page will be your Two-factor authentication status. To get started with setting it up, click on the Set up two-factor authentication button.

4. You will then be presented with a brief overview of what Two-factor authentication is and you will be given the choice of Set up using an app (which I recommend) or Set up using SMS. Using an app is by far the easiest, and if you have a smartphone or tablet, you can download an authenticator application from the applicable app store. From there on, follow the prompts that GitHub give you to complete the Two-factor authentication setup.
5. After you have completed the setup, your Two-factor authentication will be switched on.

## Two-factor authentication

Status: On ✓

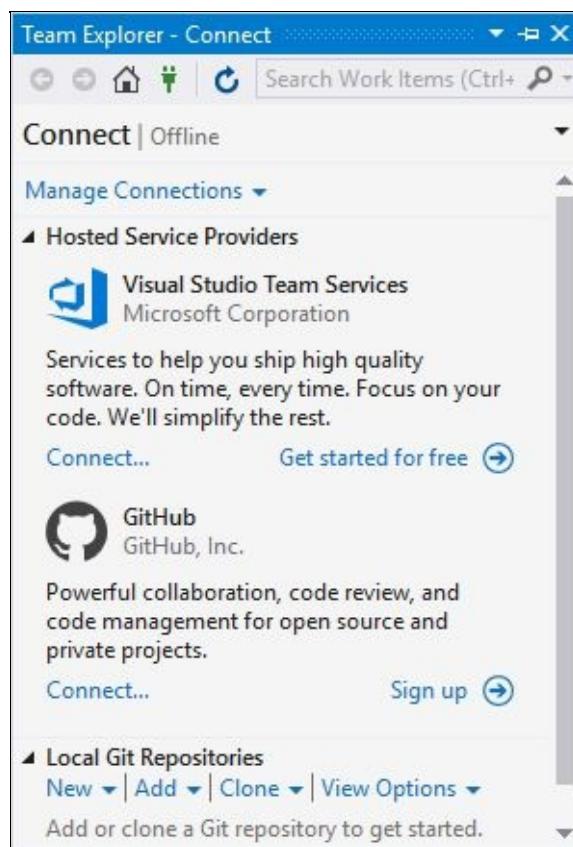

Edit

Save your recovery codes in a safe place. They will allow you to access your account if you ever lose your phone.

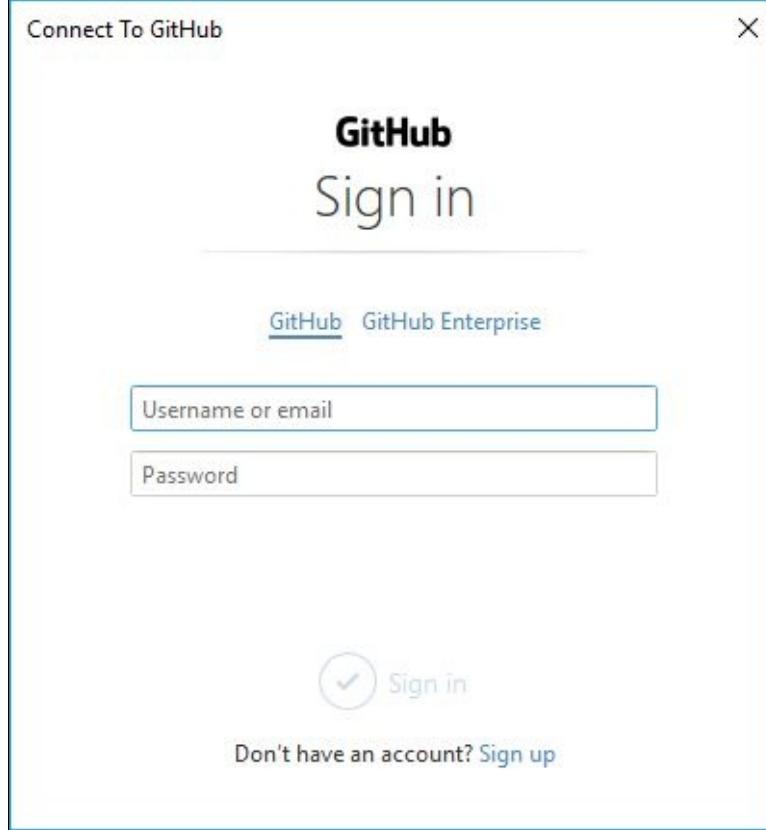

# How to do it...

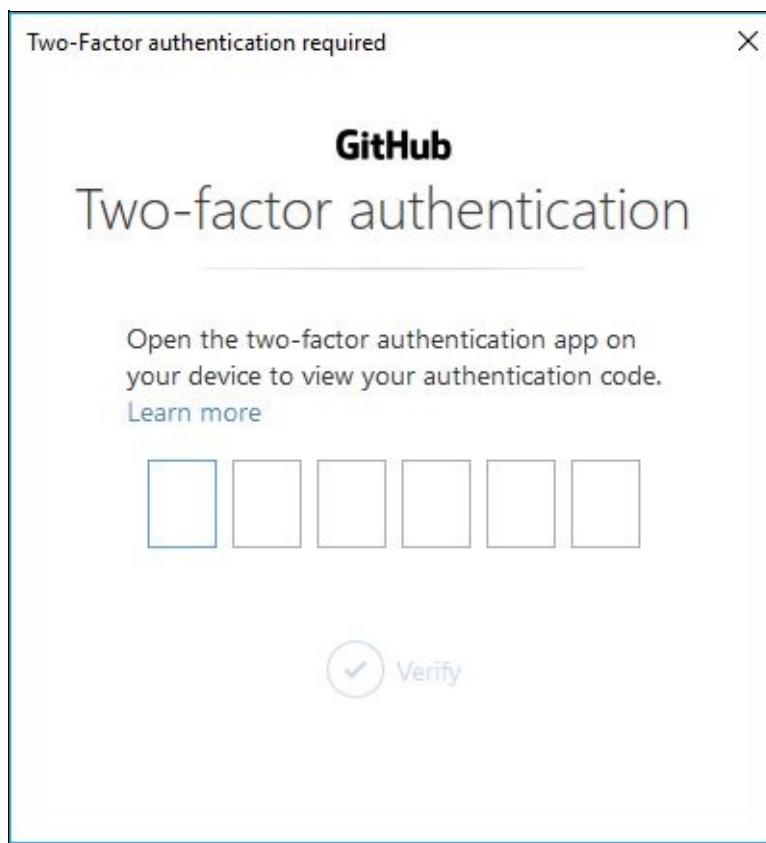

1. Adding the GitHub extension to Visual Studio is easily done by downloading the visx from the following link and installing it: <https://visualstudio.github.com/downloads/GitHub.VisualStudio.vsix>.
2. Assuming that you have an existing application you want to add to GitHub, the process of adding it to a new repository is quite simple. I have simply created a console application with nothing but the template code, but you can add any project type and size to GitHub.
3. On the View menu in Visual Studio 2017, select the Team Explorer option.
4. You will be presented with two options under the Hosted Service Providers section. For now, we will select GitHub and, seeing as we already have an account, we will click on Connect...

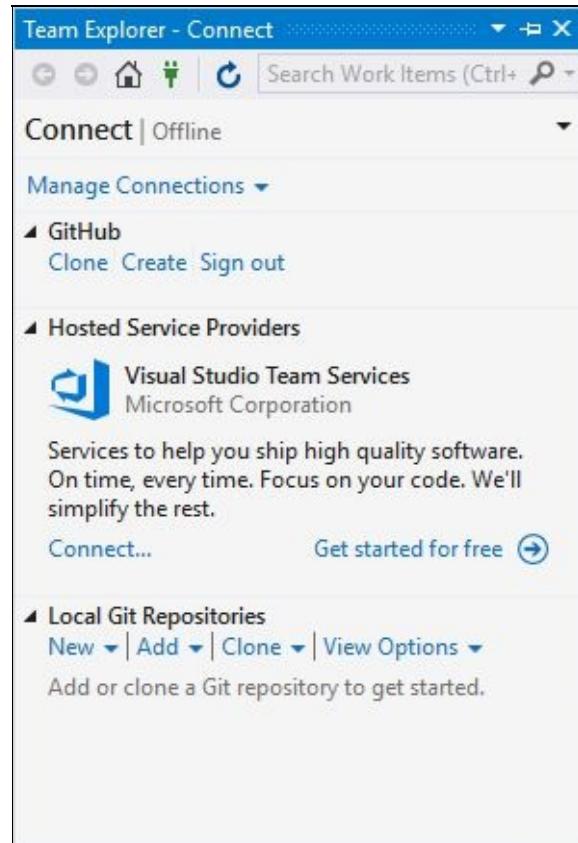

5. You will now be presented with the GitHub login page. You are also offered the chance to sign up from here if you do not have an existing GitHub account:

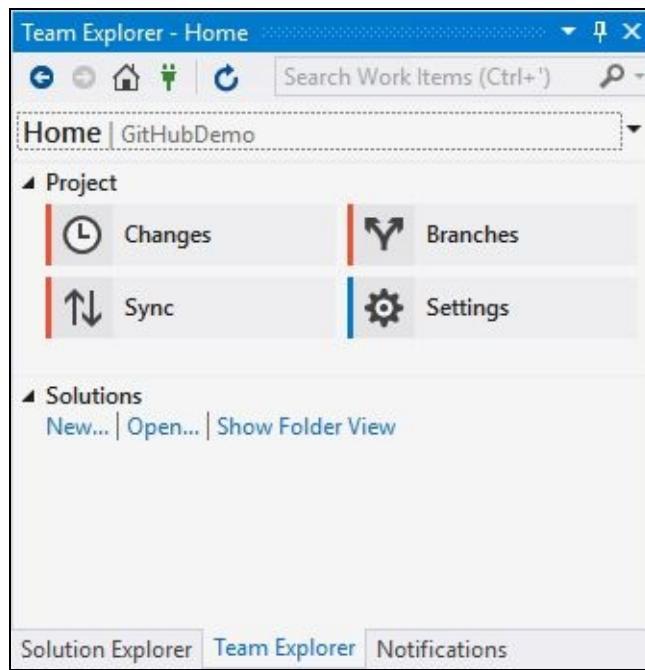

6. Because I have Two-factor authentication set up on my GitHub account, I am prompted to use my authenticator application to enter the generated authentication code and authenticate myself:

7. After you have been authenticated, you will return to the Manage Connections screen. If your project isn't displayed under the Local Git Repositories, you can add it:

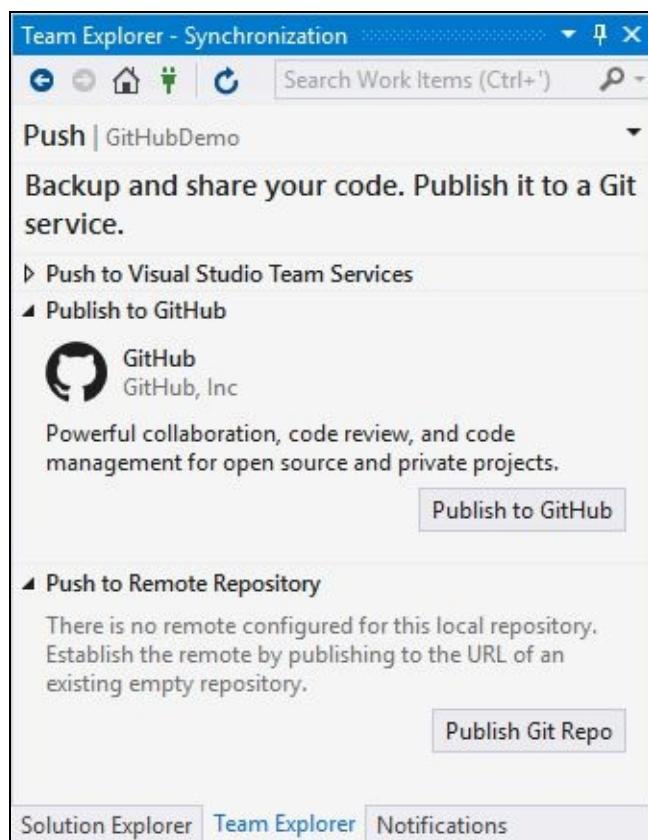

8. Next, you will want to click on the Home icon, which is a picture of a little house at the top of the Team Explorer window. From the Home screen, click on the Sync button:

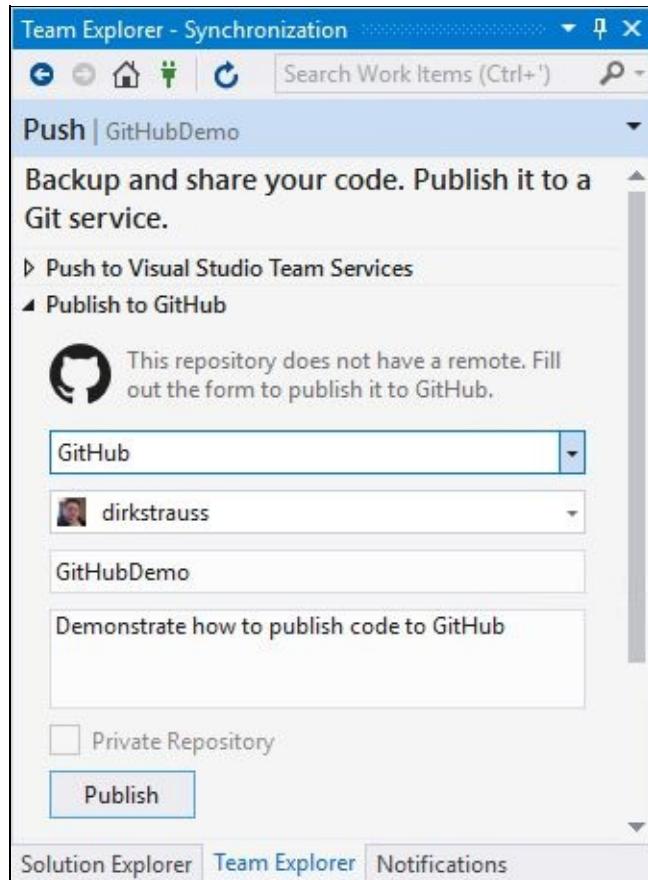

9. This will display the Publish window to you. Under GitHub, click on the Publish to GitHub button. This is going to publish your project to a new repository on GitHub.

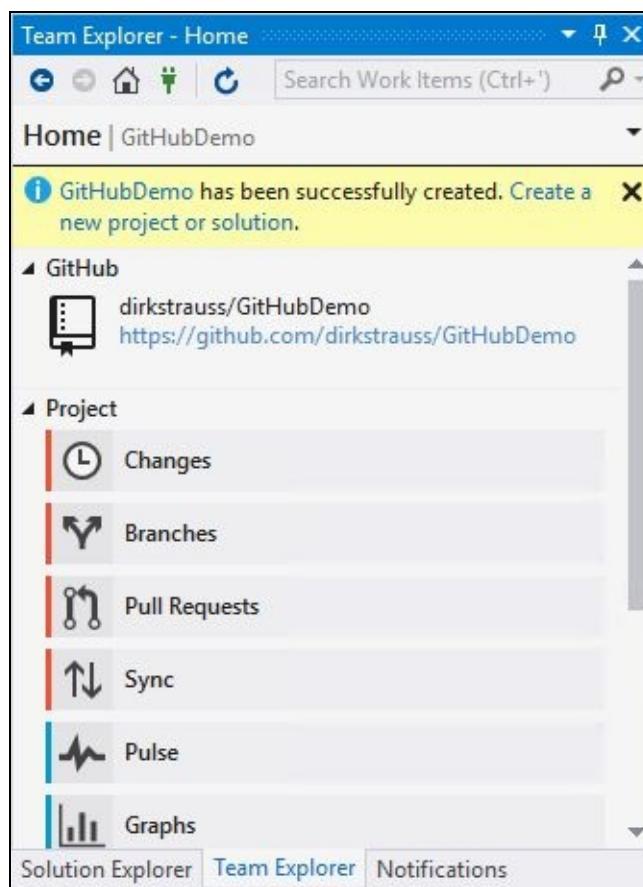

*Remember, if you are using the free GitHub, all your repositories are public. If you are writing code that can't be made public (is not open source), then sign up for one of the paid GitHub accounts that include private repositories.*

10. GitHub will then prompt you to add in the details for this publish. Because you connected to GitHub earlier, your username will already be selected in the drop-down menu. When you are ready, click on Publish:

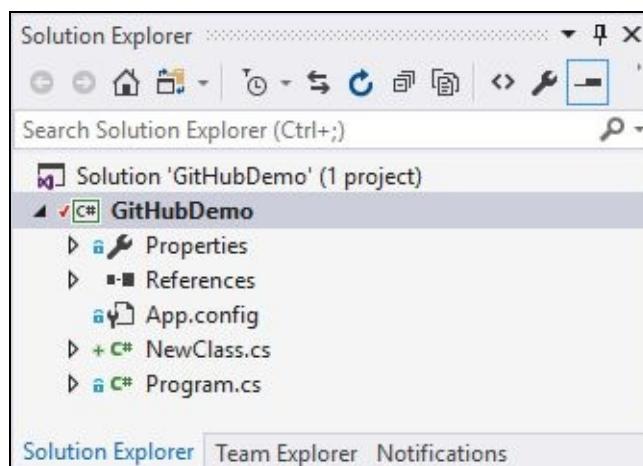

11. When the project has been published to GitHub, you will automatically be returned to the Home screen:

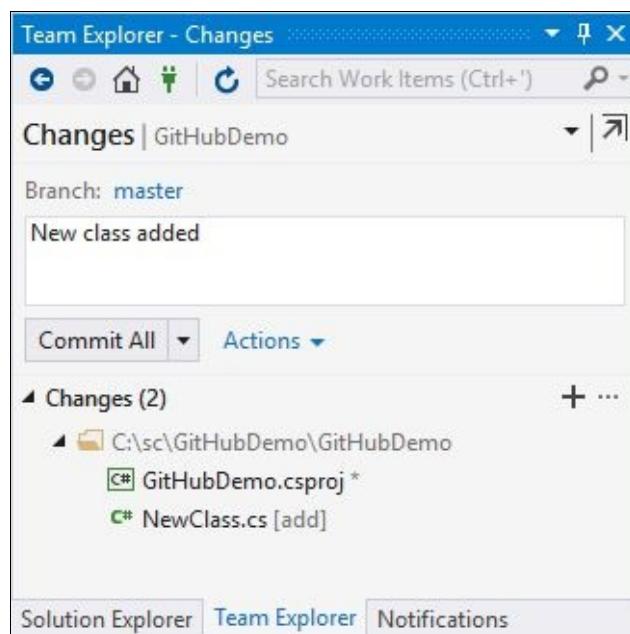

12. Looking at your GitHub account online, you will see that the project has been added:

A screenshot of a GitHub user profile page. At the top, it shows "Overview", "Repositories 4", "Stars 2", "Followers 1", and "Following 2". Below this, there's a section titled "Popular repositories" with four cards. The first card is for "Resume" (GitHub Resume). The second card is for "Extension-Methods" (Helper class to provide some convenient Extension Methods to your projects, written in C#). The third card is for "DeveloperCommunity" (Code from the Developer Community YouTube channel). The fourth card is for "GitHubDemo" (Demonstrate how to publish code to GitHub, written in C#).

13. Next, let's go and make some changes to the `GitHubDemo` application. Just go ahead and add a new class to your project. I called mine `NewClass.cs`, but you can call yours whatever you like.
14. You will notice that as soon as a change is made to your project, that the solution will mark the changed items with a red tick. Your class is marked with a green plus sign:

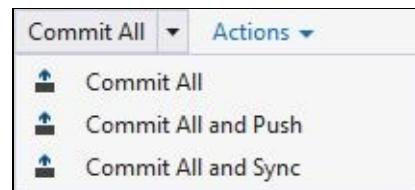

15. To add the changes to your GitHub repository, you can follow two routes. The first option is to go to the Team Explorer - Home window and click on the Changes button.
16. The second (and in my opinion more convenient) option, is to right-click the solution in Solution Explorer and click on the Commit... menu item from the context menu.
17. GitHub might ask you for your user information the first time you perform a commit.
18. Before you are allowed to commit your changes, you must fill in the required commit message. In a real team project, be as descriptive as possible in your commit message. Consider using task item code (or backlog codes) to uniquely identify the code being added. This will save your (or another developer's) bacon sometime in the future, I guarantee it:

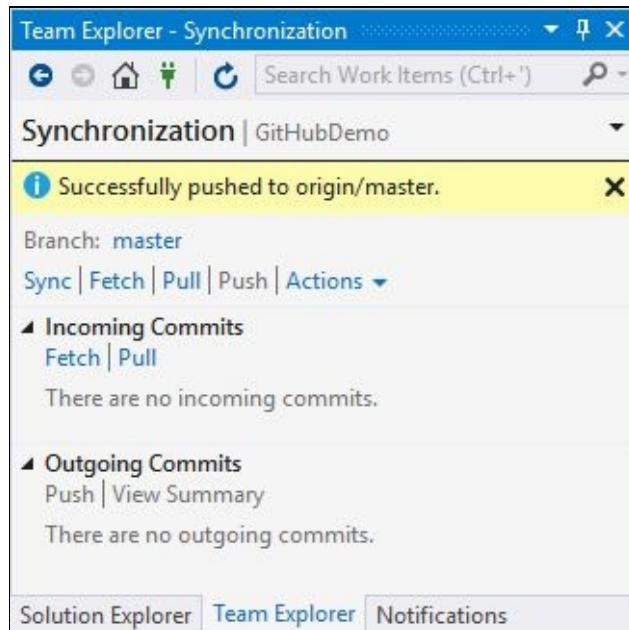

19. One important thing to note is that you have three commit options available to you if you click on the down arrow next to the Commit All button. The Commit All button will just record the changes you make on your local machine. In other words, the change will not be reflected in the remote repository. The Commit All and Push button will record the changes on your local machine and push those changes to your remote GitHub repository. The Commit All and Sync button will record the changes on your local machine, then it will pull any changes from the remote repository, and finally it will do the push. You will want to do this if you are working in a team. For this recipe, however, I

will just do a Commit All and Push, seeing as I am the only developer working on this repo:

20. When the commit has completed, the Team Explorer - Synchronization window will notify you of the successful commit:

21. Heading over to GitHub online, you will see the newly pushed changes reflected in your GitHub repository, along with the commit message:

A screenshot of a GitHub repository page for 'GitHubDemo'. The top navigation bar includes 'This repository', 'Search', 'Pull requests', 'Issues', 'Gist', and icons for notifications, forks, and settings. The main header shows the repository name 'dirkstrauss / GitHubDemo' and metrics: 1 unwatched, 0 stars, 0 forks. Below the header, there are buttons for 'Code', 'Issues 0', 'Pull requests 0', 'Projects 0', 'Wiki', 'Pulse', 'Graphs', and 'Settings'. A dropdown for 'Branch: master' is set to 'GitHubDemo / GitHubDemo /'. A toolbar at the bottom right offers 'Create new file', 'Upload files', 'Find file', and 'History'. The main content area lists recent commits: 'dirk\_developer New class added' (latest commit, 2 minutes ago), 'Properties' (Initial Commit, 31 minutes ago), 'App.config' (Initial Commit, 31 minutes ago), 'GitHubDemo.csproj' (New class added, 2 minutes ago), 'NewClass.cs' (New class added, 2 minutes ago), and 'Program.cs' (Initial Commit, 31 minutes ago).

22. GitHub is a fantastic source control solution for any developer. Consider creating an open source

project. It is more beneficial than you might imagine.

*More and more these days, prospective employers are reviewing developers' GitHub repos when considering applicants for developer positions. Keep that in mind, because a GitHub repo is a resume in itself.*

# How it works...

The free GitHub account allows you to create public repositories. This means that anyone is able to search for, view, and clone your project from GitHub to their own desktop. This is the central idea behind GitHub. This is obviously a key factor for indie developers and corporates that don't want to spend money. Corporates can afford it more than an indie developer, but I think that some companies prefer to roll their own, rather than use a service provider hosted in the cloud somewhere. This means that they prefer to keep the source control under their control by setting up a source control system on their own corporate servers. Having GitHub as an option for indie developers is an awesome solution. For those that require private repos, the fee isn't a stumbling block either.

# **Working as a team using GitHub, handling and resolving conflicts in code**

GitHub and Team Services really come into their own when working in teams. The effect of collaborative effort is quite powerful. Sometimes though, it can be a bit challenging. Let us have a look at using GitHub to work in a team setup.

# Getting ready

We will be using the existing GitHubDemo app checked in to GitHub. Let's assume that a new developer (let's call him John) has joined the team. Before you can let him push code to your branch, you need to add him as a collaborator. To do this, log in to GitHub and click on the Settings tab in your GitHubDemo repository. Click on Collaborators in the menu to the left.

You can then search for collaborators to add by entering their GitHub username, full name, or e-mail address:

The screenshot shows the GitHub repository settings page for 'dirkstrauss / GitHubDemo'. The 'Collaborators' tab is selected in the sidebar. A message states: 'This repository doesn't have any collaborators yet. Use the form below to add a collaborator.' Below is a search input field containing 'johndevelops' and a blue button labeled 'Add collaborator'.

When you are done, click on the Add collaborator button to add John as a collaborator to your project:

The screenshot shows the GitHub repository settings page for 'dirkstrauss / GitHubDemo'. The 'Collaborators' section now displays a message: 'Awaiting johndevelops's response'. It includes a 'Copy invite link' button and a 'Cancel invite' button. Below is a search input field containing 'johndevelops' and a blue button labeled 'Add collaborator'.

John will receive an e-mail and will first need to respond to your invitation to collaborate.

dirkstrauss invited you to collaborate

[Accept invitation](#)

[Decline](#)

Is this user sending spam or malicious content? You can [block @dirkstrauss](#).

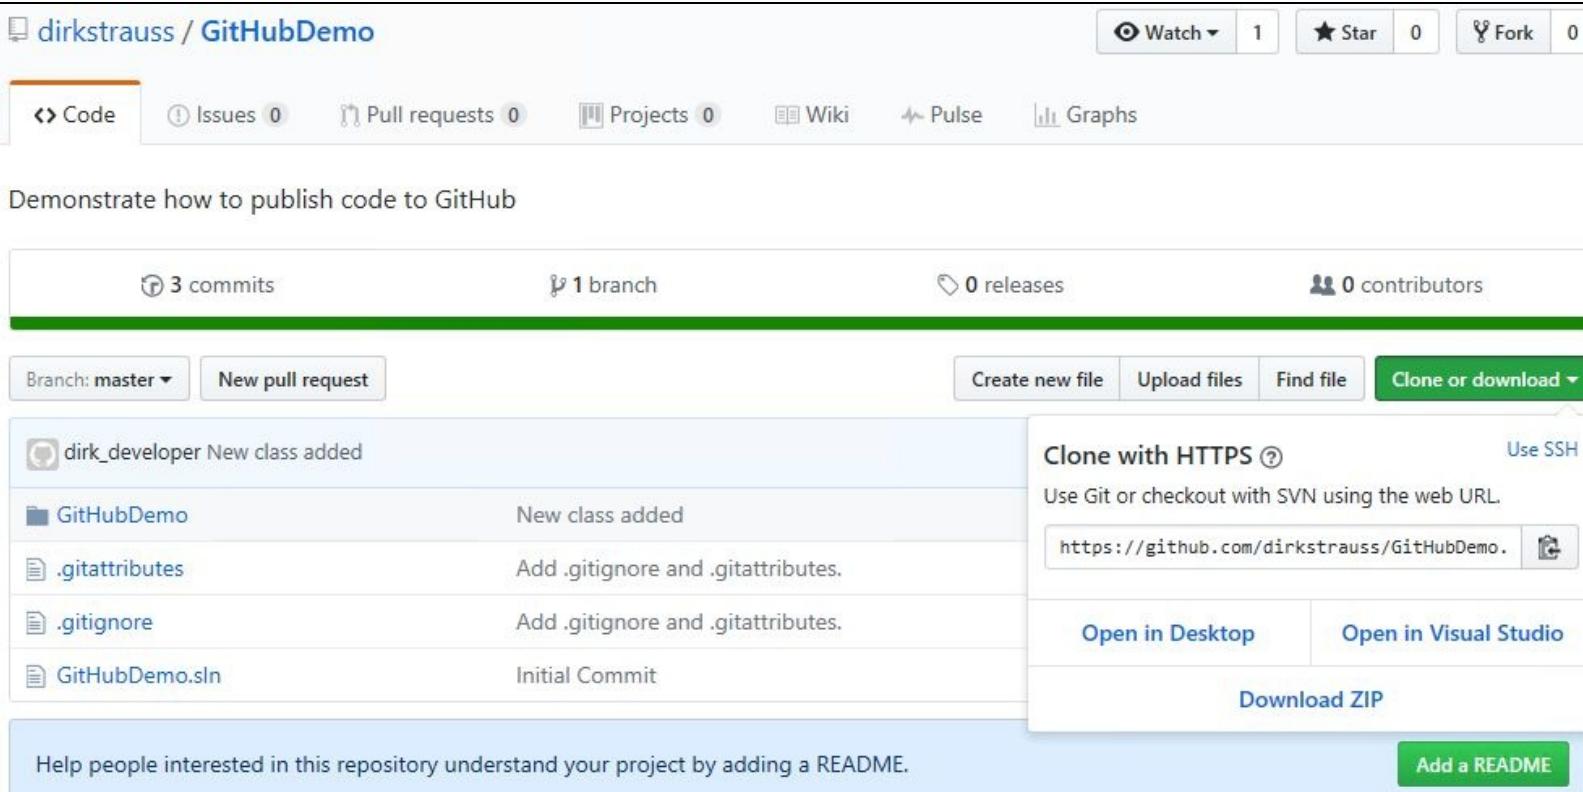

# How to do it...

1. John goes about setting up his Visual Studio environment, including getting connected to GitHub, by clicking on Team in the menu and clicking on Manage Connections....
2. He logs in to GitHub with his e-mail address and password.

*Take note that if you have just signed up to GitHub, you will need to click on the verification e-mail sent to the e-mail address you specified when signing up. Without verifying your e-mail address, you will not be able to log in from Visual Studio.*

3. After connecting, John sees his GitHub details loaded:
4. He now wants to work on the GitHubDemo application and finds it on GitHub by searching for it by name:

The screenshot shows a GitHub repository page for 'GitHubDemo' owned by 'dirkstrauss'. The repository has 3 commits, 1 branch, 0 releases, and 0 contributors. It contains files like 'GitHubDemo.csproj', '.gitignore', and 'GitHubDemo.sln'. On the right, there's a 'Clone with HTTPS' section with a URL: <https://github.com/dirkstrauss/GitHubDemo>, and options to 'Open in Desktop', 'Open in Visual Studio', or 'Download ZIP'.

dirkstrauss / GitHubDemo

GitHubDemo.sln Initial Commit	<a href="#">Download ZIP</a>

Help people interested in this repository understand your project by adding a README. Add a README

5. He now copies the URL from the Clone with HTTPS textbox from the Clone or download button:

6. Back in Visual Studio, John expands the Local Git Repositories and clicks on Clone. He pastes the copied URL to the Git Repository path and specifies where the code should be cloned to on his hard drive. He then clicks on Clone:

7. When the code is cloned, it will be in the folder path John specified earlier.
8. Time to make some changes to the code. He opens the project in Visual Studio as normal. John decides to work on the `NewClass` class and adds a new function that returns a countdown integer:

The screenshot shows the Microsoft Visual Studio interface. The title bar reads "GitHubDemo - Microsoft Visual Studio". The menu bar includes File, Edit, View, Project, Build, Incredibuild, Debug, Team, Tools, Architecture, and Test. Below the menu is a toolbar with various icons. The main window shows a code editor with the file "NewClass.cs" open. The code defines a class "NewClass" with a method "CountDown" that multiplies the current second by a factor. The Solution Explorer panel on the right shows the project structure with files "Properties", "References", "App.config", "NewClass.cs", and "Program.cs". The status bar at the bottom displays "Ln 14 Col 36 Ch 36 INS" and "githubrepos master".

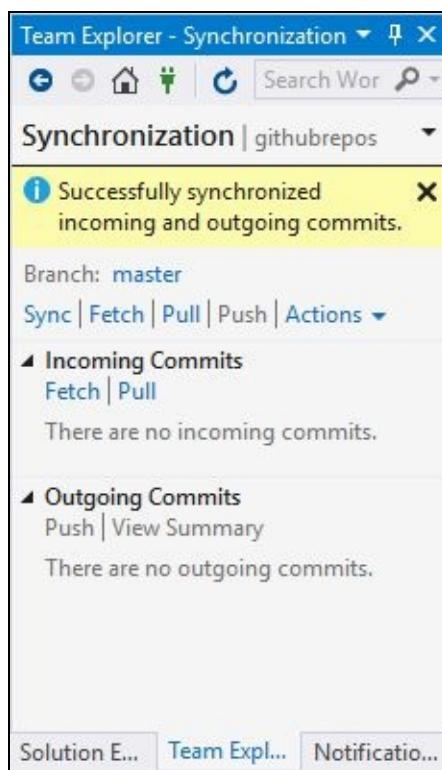

```
2  using System.Collections.Generic;
3  using System.Linq;
4  using System.Text;
5  using System.Threading.Tasks;
6
7  namespace GitHubDemo
8  {
9      class NewClass
10     {
11         public int CountDown(int factor)
12         {
13             int second = DateTime.Now.Second;
14             return second * factor;
15         }
16     }
17 }
18
```

9. After the code change is complete, John prepares to commit the code he just added to the GitHubDemo project.
10. After adding a commit message, he then clicks on Commit All and Sync.

*One important thing to note is that you have three commit options available to you if you click on the down arrow next to the Commit All button. This button will just record the changes you make on your local machine. In other words, the change will not be reflected in the remote repository. The Commit All and Push button will record the changes on your local machine and push those changes to your remote GitHub repository. The Commit All and Sync button will record the changes on your local machine, then it will pull any changes from the remote repository, and finally it will do the push.*

11. John's changes are committed to the GitHub repository:

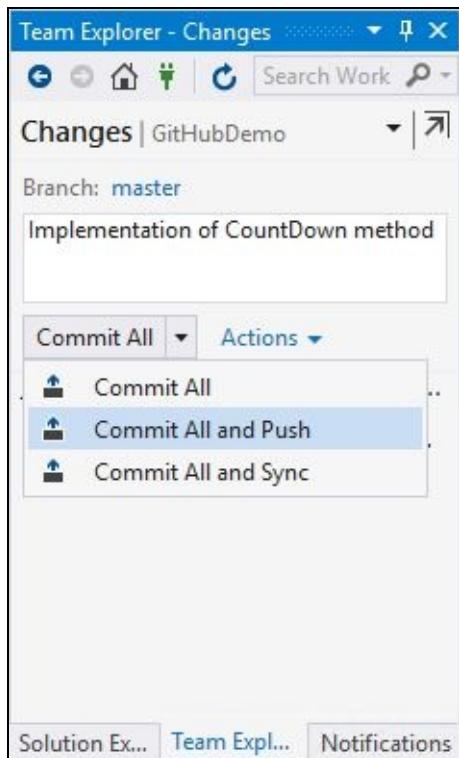

12. On the other side of the office, I am working on the same bit of code. The only problem is that I have added the same method with my own implementation of the `countDown` logic:

A screenshot of Microsoft Visual Studio showing the GitHubDemo project. The code editor displays Program.cs with the following content:

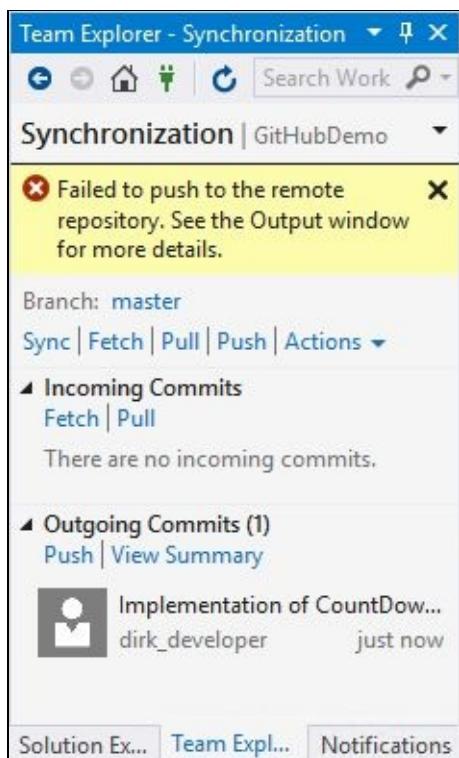

```
2  using System.Collections.Generic;
3  using System.Linq;
4  using System.Text;
5  using System.Threading.Tasks;
6
7  namespace GitHubDemo
8  {
9      O references | dirk_developer, 1 hour ago | 1 author, 1 change
10     class NewClass
11     {
12         O references | 0 changes | 0 authors, 0 changes
13         public double CountDown(double theFactor)
14         {
15             int currentHour = DateTime.Now.Hour;
16             return currentHour / theFactor;
17         }
18     }
}
```

The Solution Explorer pane shows the project structure with files GitHubDemo.cs, App.config, NewClass.cs, and Program.cs. The NewClass.cs file is selected. The Properties pane is visible on the right.

13. I get ready and commit my changes to GitHub:

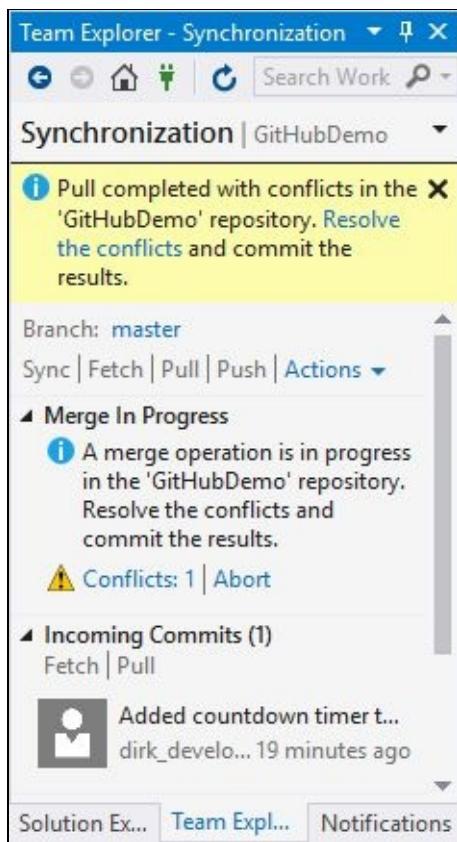

14. GitHub immediately prevents me from doing this. This is because if my code is pushed, the earlier commit by John will be lost. GitHub has a great help file on the subject in GitHub Help at <https://help.github.com/articles/dealing-with-non-fast-forward-errors/>.

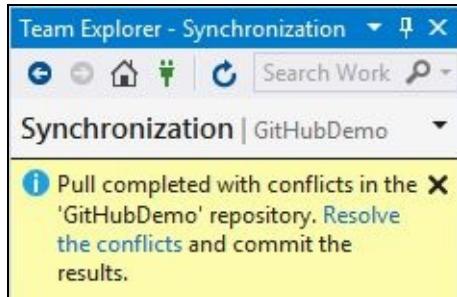

The Output window contains a more descriptive error message: *"Error encountered while pushing to the remote repository: rejected Updates were rejected because the remote contains work that you do not have locally. This is usually caused by another repository pushing to the same ref. You may want to first integrate the remote changes before pushing again."*

15. To resolve this, click on Pull to get the latest commit that John did. Your code will then be in a conflicted state. This sounds bad, but it isn't. It is putting you in control of the decision on which

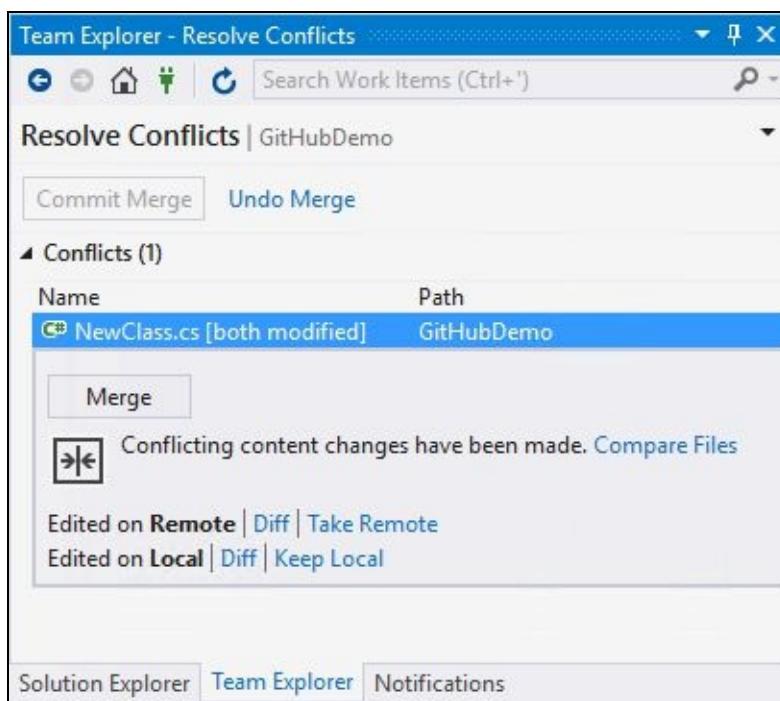

code will be used. You can see that the pull shows that there are conflicted files and also the incoming commit message that John added:

16. To view the conflicts, click on the Resolve the conflicts link in the message pop-up:

17. You will then see the Resolve Conflicts screen listing the conflicted files. Clicking on a file will expand it into a short summary and action options screen. It is always prudent to click on the Compare Files link to see the difference between the files in conflict:

18. The differences in code are immediately evident. The process you follow from here on is subject to how you work together as a team. Usually, the conflict can be quite complex and it is always a good idea to speak to the developer concerned about the way forward:

```

Diff - GitHubDemo/.../NewClass.cs;Local ▾ X
GitHubDemo/NewClass.cs;Remote
GitHubDemo/NewClass.cs;Local
CountDown(int factor)
CountDown(double theFactor)

```

```

1 using System;
2 using System.Collections.Generic;
3 using System.Linq;
4 using System.Text;
5 using System.Threading.Tasks;
6
7 namespace GitHubDemo
8 {
9     class NewClass
10    {
11        public int CountDown(int factor)
12        {
13            int second = DateTime.Now.Second;
14            return second * factor;
15        }
16    }
17 }
18

```

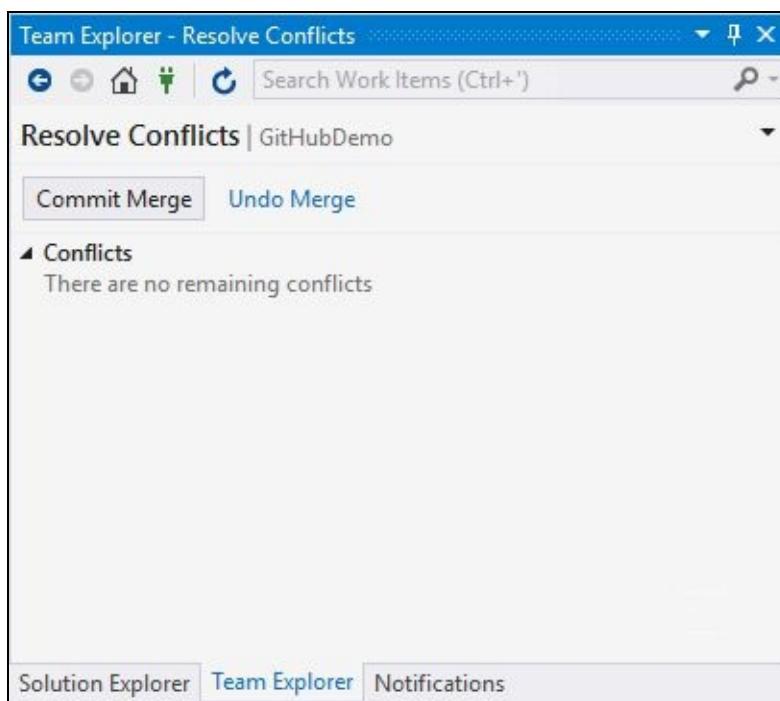

```

1 using System;
2 using System.Collections.Generic;
3 using System.Linq;
4 using System.Text;
5 using System.Threading.Tasks;
6
7 namespace GitHubDemo
8 {
9     class NewClass
10    {
11        public double CountDown(double theFactor)
12        {
13            int currentHour = DateTime.Now.Hour;
14            return currentHour / theFactor;
15        }
16    }
17 }
18

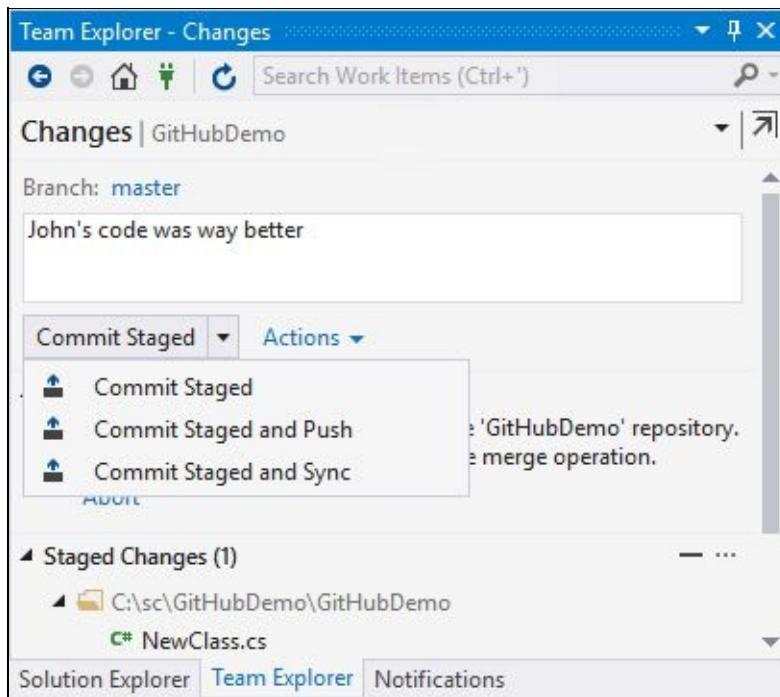

```

100 % ▾ < > ▾ Removed Added Help

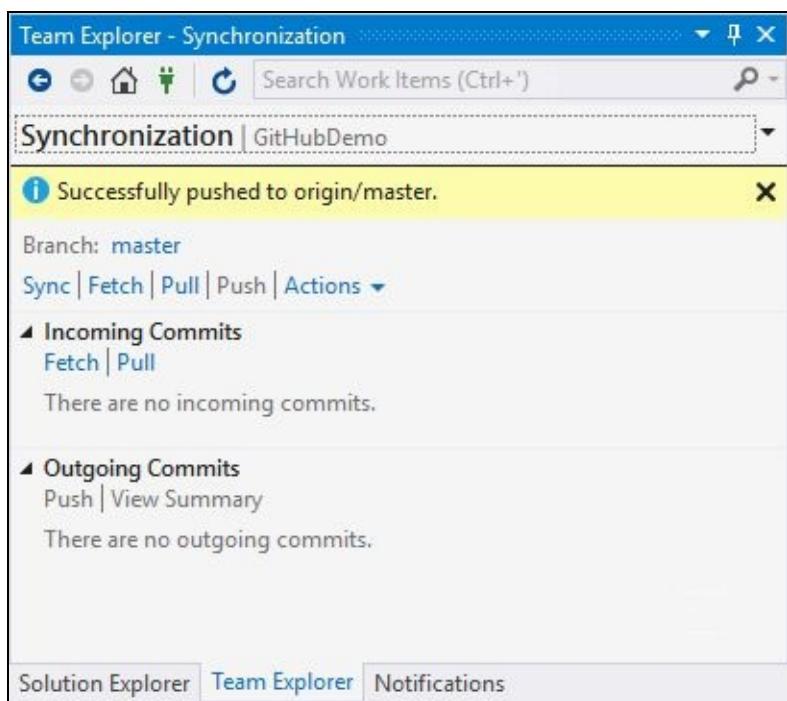

19. In this case, John and I decided that his code was better and more concise. So the decision was made to simply click on Take Remote and use John's code. When you have clicked on the link, you need to click on Commit Merge:

20. After adding a commit message, you can then push your code to the repo. In this case, I simply replaced all my code with John's, but there might be situations when you will be using some of your code and some of another developer's code. GitHub allows us to easily handle these conflicts:

21. After pushing the code to the remote, GitHub notifies you that the code has successfully been synchronized:

# How it works...

GitHub takes the pain out of committing, resolving conflicts, and merging code. It is, without a doubt, an essential tool in any developer's toolkit and essential for development teams. Even if you are not using it professionally, it's a great idea to create a repo for yourself. Start using it to check on the pet projects you work on after hours. Expanding your knowledge beyond what you work with on a day-to-day basis will make you a better developer.

# Creating a Mobile Application in Visual Studio

Visual Studio is the *tour de force* of **integrated development environments (IDEs)**. There is no doubt about that. You, as a developer, are able to be as versatile as you like by creating applications for a wide range of platforms. One of these platforms is mobile development. Developers are starting to create mobile applications, but don't want to use a different IDE. With Visual Studio, you don't have to. It will allow you to create Android and (now with **Xamarin**) iOS and Mac applications too.

This chapter will, therefore, take a look at the following concepts:

- Installing Xamarin and other required components on your Windows PC and Mac
- Creating a mobile application using Apache Cordova
- Creating an iOS application using Xamarin.Forms and Visual Studio for Mac

# Introduction

If you have not heard about Xamarin, we encourage you to do a Google search for this tool. Traditionally, developers needed to use **Xcode** or **NetBeans** to create iOS and Android applications. The challenge for developers was that it meant learning a new programming language. If you, for example, created an application that you wanted to deploy to iOS, Android, and Windows, you needed to know Objective-C or Swift, Java, and a .NET language.

This also created additional challenges for development, because it meant having to maintain multiple code bases. If a change was to be made in the Windows version of the application, it also had to be made to the iOS and Android code base. Sometimes companies would manage different development teams for each platform. You can imagine the complications involved in managing a change across multiple teams on multiple platforms. This is especially true if you are dealing with a large code base.

Xamarin solves this problem by allowing .NET developers to use standard .NET libraries to create iOS and Android applications using Visual Studio. You, as a .NET developer, can now use the skills you already have to accomplish this. In a nutshell, you would create a shared library for your applications and then have different facades for the different platforms. A second option is to use Xamarin.Forms to create one Visual Studio project and target all three platforms. This makes it very easy to for developers to target multiple platforms.

# Installing Xamarin and other required components on your Windows PC and Mac

How does Xamarin work exactly? It does seem like magic, right? I mean, writing C# in Visual Studio and compiling a native iOS, Mac, or Android application on the other side does seem magical. A lot of technology has gone into giving developers the ability to do this. With iOS and Mac applications, the process is somewhat involved. One thing to be aware of if you want to target iOS or Mac is that you will need to use a Mac in order to build your iOS applications. There are services out there that make Macs available for remote testing and compilation (such as MacinCloud, <http://www.macincloud.com/>). These, however, do incur a monthly cost. When Xamarin compiles your C# code, it does so against a special subset of the Mono framework.

*Mono is sponsored by Microsoft and is an open source implementation of the .NET Framework. This is based on the ECMA standards for C# and the **Common Language Runtime**. For more information on the Mono framework, take a look at <http://www.mono-project.com/>.*

Looking at iOS specifically, this special subset includes libraries that allow access to iOS platform-specific features. The Xamarin.iOS compiler will take your C# code and compile it into an intermediate language called ECMA CIL. This **common intermediate language (CIL)** is then compiled a second time into native iOS code that an iPhone or iPad can run. You can then also deploy this to a simulator for testing.

Now, you might be wondering why a Mac is needed to compile your application? Why can't it all just happen from within Visual Studio? Well, this is due to a (quite clever) restriction imposed by Apple on the ability of the iOS kernel to generate code at runtime. It simply does not allow that to happen. As you know (this is the extremely simplified explanation), when your C# source code is compiled for testing it is compiled into intermediate language. The **just-in-time (JIT)** compiler then compiles the intermediate language into assembly code that is appropriate for the architecture you are targeting. Because the iOS kernel does not allow this on-demand compilation by a JIT compiler, the code is statically compiled using **ahead-of-time (AOT)** compilation.

*To view the limitations of Xamarin.iOS, take a look at the following link:*

*[https://developer.xamarin.com/guides/ios/advanced\\_topics/limitations/](https://developer.xamarin.com/guides/ios/advanced_topics/limitations/)*

*For a list of available assemblies in Xamarin.iOS, Xamarin.Mac, and Xamarin.Android, take a look at the following support document:*

*<https://developer.xamarin.com/guides/cross-platform/advanced/available-assemblies/>*

The technology behind this is quite impressive. It is no wonder that Microsoft acquired Xamarin and included it as part of Visual Studio. Giving developers this array of choice for cross-platform development is what Microsoft is all about: empowering developers to create world-class applications.

# Getting ready

We are going to look at getting Xamarin installed on your Windows PC running Visual Studio 2017 in this recipe. Xamarin can be installed as part of a workload when Visual Studio 2017 is installed. For now, let's assume that Xamarin has not been installed and that you need to do that now, after you have installed Visual Studio. Go to the Visual Studio website at <https://www.visualstudio.com/> and download the installer for the version of Visual Studio you installed.

*You can also run the installer from the New Project dialog screen in Visual Studio 2017. If you collapse the installed templates, you will see a section that allows you to open the Visual Studio Installer.*

You will also need to install Xcode, which is Apple's development environment. This can be downloaded for free from the Mac App Store.

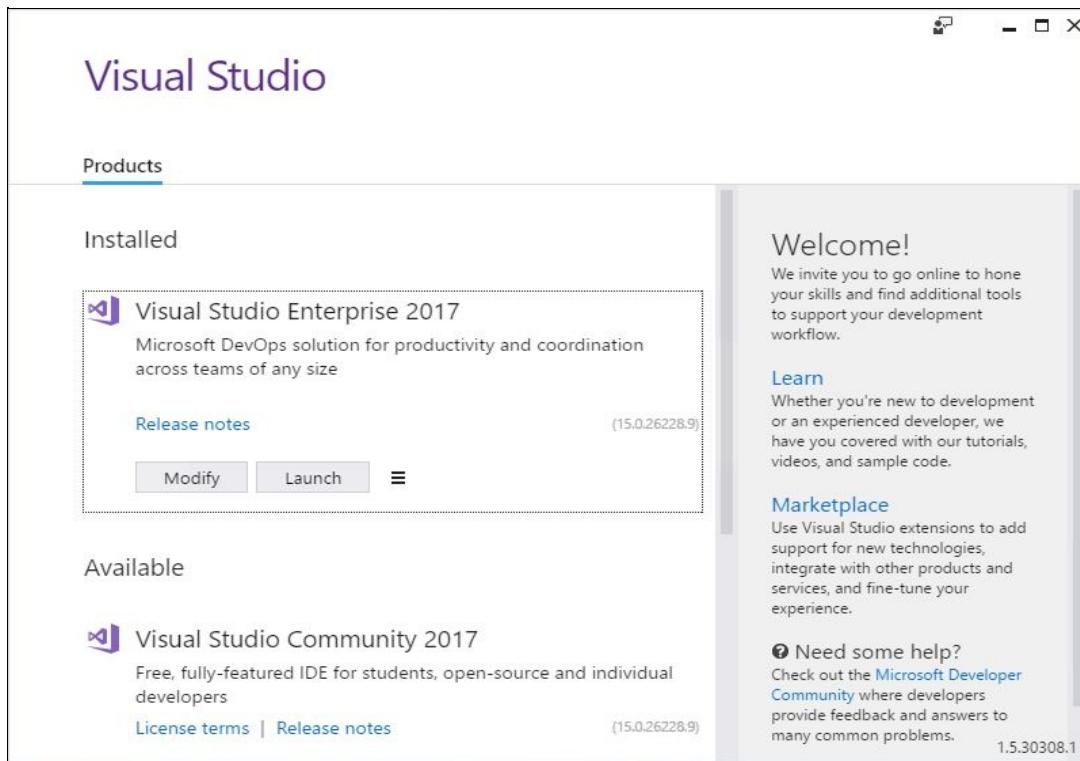

*Note that you will need to have an iTunes login to download Xcode and complete setting up your Mac. Chances are, if you have a Mac, you most definitely will have an iTunes login too.*

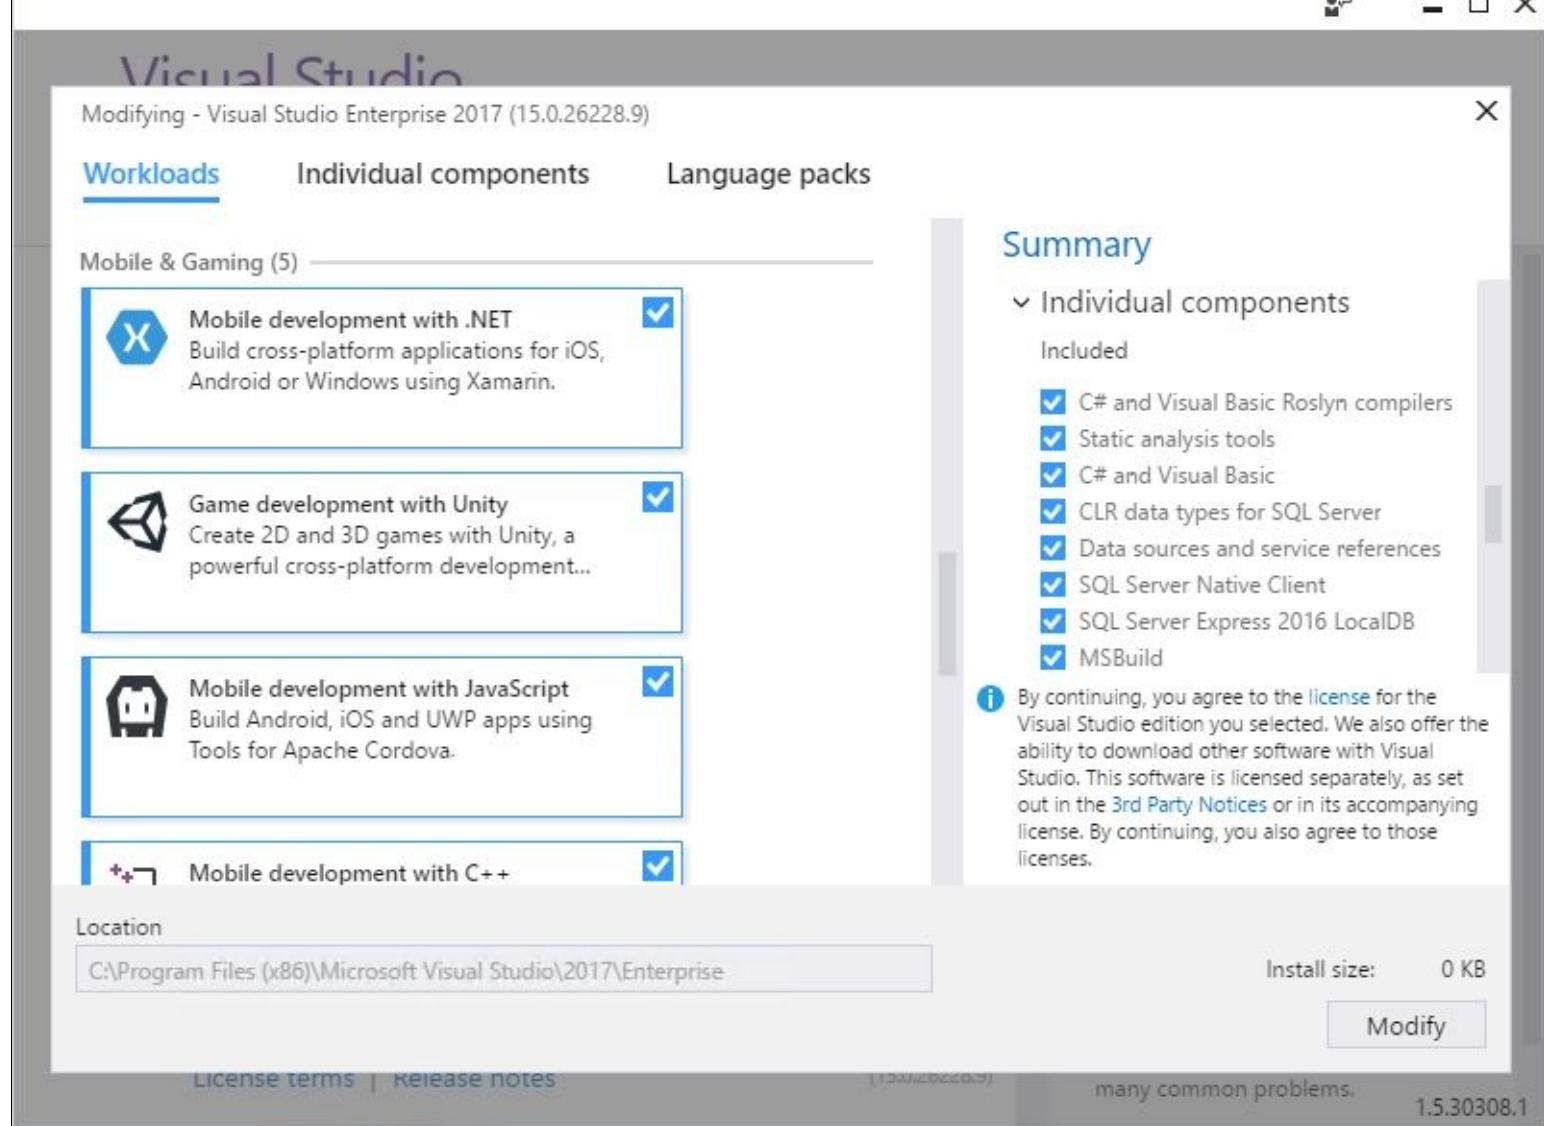

# How to do it...

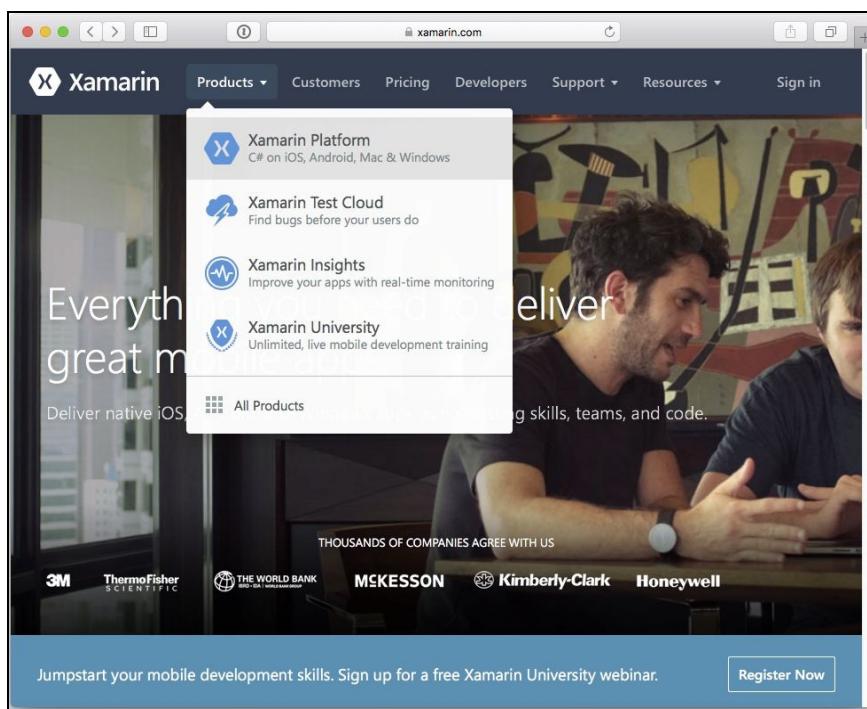

1. Double-click on the installer you downloaded from the Visual Studio website. You will see that your version of Visual Studio 2017 is displayed and a Modify button is visible. Click on the Modify button:

2. This will display the available workloads for you. Under the Mobile & Gaming section, ensure that you select Mobile development with .NET. Then, click on the Modify button in the lower-right corner:

3. There is also a second step we need to take if we want to use Xamarin to target iOS applications. We have to install the required software on a Mac. Head on over to Xamarin's website on your Mac. The URL is <https://www.xamarin.com/>. Click on the Products drop-down and select Xamarin Platform from the list:

4. You can also access the required page by going to <https://www.xamarin.com/platform>. Clicking on the Download now for free button will install something called **Xamarin Studio Community** on your Mac. You need to be aware that when installed on a Mac, Xamarin Studio cannot create Windows apps. It will only allow you to create iOS and Android apps on a Mac. Along with Xamarin Studio, you will also get the Xamarin Mac Agent (previously called the Xamarin build host). This is a required component so that you can link your PC to your Mac in order to build your iOS application. Lastly, the PC and Mac must also be able to connect to each other over a network (more on this later).
5. After downloading the installer on the Mac, the installation is straightforward. You will notice that there are a few options to choose from the installation screen: Xamarin.Android, Xamarin.iOS, Xamarin.Mac, and Xamarin Workbooks & Inspector. If you wanted to target Android as a platform, you would install Xamarin.Android. To target iOS (iPhone or iPad), you will need to select Xamarin.iOS. To create fully native Mac applications, you must select Xamarin.Mac. Lastly, Xamarin Workbooks & Inspector gives developers an interactive C# console that integrates with app debugging to aid developers when inspecting running apps. For now, we're only interested in Xamarin.iOS. Just follow the screen prompts and complete the installation. Depending on your selection, the installer will download the required dependencies and install that on your Mac. Depending on your Internet connection, you might want to go get a cup of coffee:

## Which components would you like to install?

 Xamarin.Android 7.1.0   Xamarin.iOS 10.4.0

 Xamarin.Mac 3.0.0   Xamarin Workbooks & Inspector 1.1.2

► Dependencies (3)

Continue

6. Lastly, if you have not installed Xcode from the Mac App Store, you should do so now before continuing:

Mac

iPad

iPhone

Watch

TV

Music

## Xcode

**By Apple****Essentials**

Open the Mac App Store to buy and download apps.

### Description

Xcode includes everything developers need to create great applications for Mac, iPhone, iPad, Apple TV, and Apple Watch. Xcode provides developers a unified workflow for user interface design, coding, testing, and debugging. The Xcode IDE combined with the Swift programming language make developing apps easier and more fun than ever.

[Apple Web Site](#) [Xcode Support](#) [Application Licence Agreement](#)[...More](#)

### What's New in Version 8.2.1

Xcode 8.2.1 includes Swift 3, and SDKs for iOS 10.2, watchOS 3.1, tvOS 10.1, and macOS Sierra 10.12.2.

Xcode 8.2.1 fixes an issue where incorrect Swift version warnings were displayed.

Updated: 19 December 2016

# How it works...

The steps we took previously when installing Xamarin will allow us to do target Mac, iOS, and Android (if we selected Xamarin.Android) platforms when developing cross-platform. Previously (before Visual Studio 2015), developers had to learn a new IDE in order to skill themselves up to create applications for other platforms. Personally, I find Xcode (the Apple developer IDE for creating native iOS and Mac applications) a bit of a learning curve. It's not because it is too complicated, but rather because it obviously works differently than what I am used to in Visual Studio. If you are serious about learning another programming language and want to go the Xcode route, take a look at Swift. It is a superb language and one that I found much easier to relate to C# than Objective-C, for example.

If, however, you would rather stick to what you know and are comfortable with, then Xamarin is your best choice for developing cross-platform applications. You also do not have to go out and buy a MacBook to compile your applications on. A Mac mini is more than enough when you want to start developing for iOS and Mac. It is an investment in your development toolset that will stand you in good stead. There are also cloud options (such as MacinCloud) available to you as a developer. With Xamarin, you can stick with C# and develop in an environment that you are familiar with.

There is a third and final option available to developers, and this is one we will be taking a look at in the final recipe of this chapter. The steps in this recipe are for when you need to create applications on your Windows PC and compile them on your Mac or MacinCloud solution.

# Creating a mobile application using Apache Cordova

Creating a mobile application using Apache Cordova is not complex at all. If you are familiar with web development, then this will feel quite natural to you. For those of you that have not developed web applications before, this will help you to familiarize yourself with this process. This is because at the very essence of Cordova lies a web application. You reference files such as JS files and CSS files and you work with an `index.html` file that you can debug in a browser.

Cordova applications offer you the flexibility of targeting iOS, Android, or Windows applications. This recipe will illustrate a simple application that displays the current date when the user clicks on a button in the app.

# Getting ready

You will need to have installed the Mobile development with JavaScript workload as part of the Visual Studio 2017 installation process. For now, let's assume that you did not install it when you installed Visual Studio 2017 and now need to run the installer again.

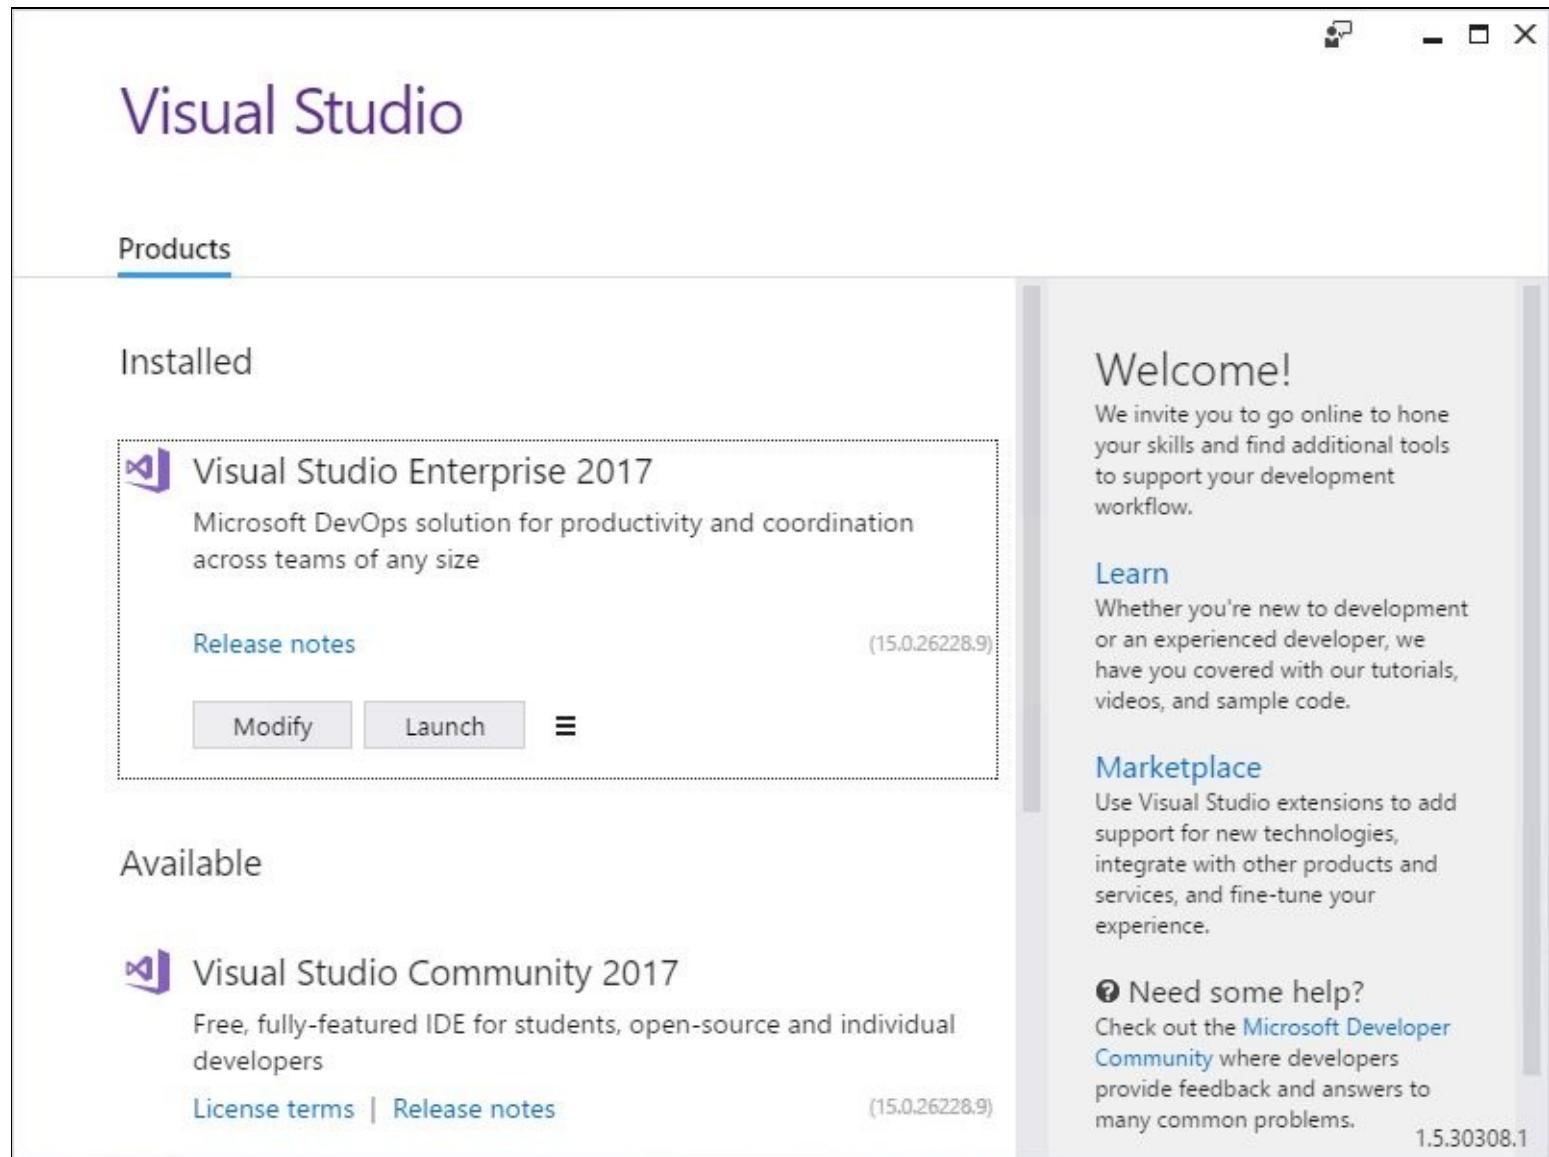

*You can also run the installer from the New Project dialog screen in Visual Studio 2017. If you collapse the installed templates, you will see a section that allows you to open the Visual Studio Installer.*

Go to the Visual Studio website at <https://www.visualstudio.com/> and download the installer for the version of Visual Studio you have installed. Also take note that you will need to have Google Chrome installed on your machine in order to launch the Cordova application simulator.

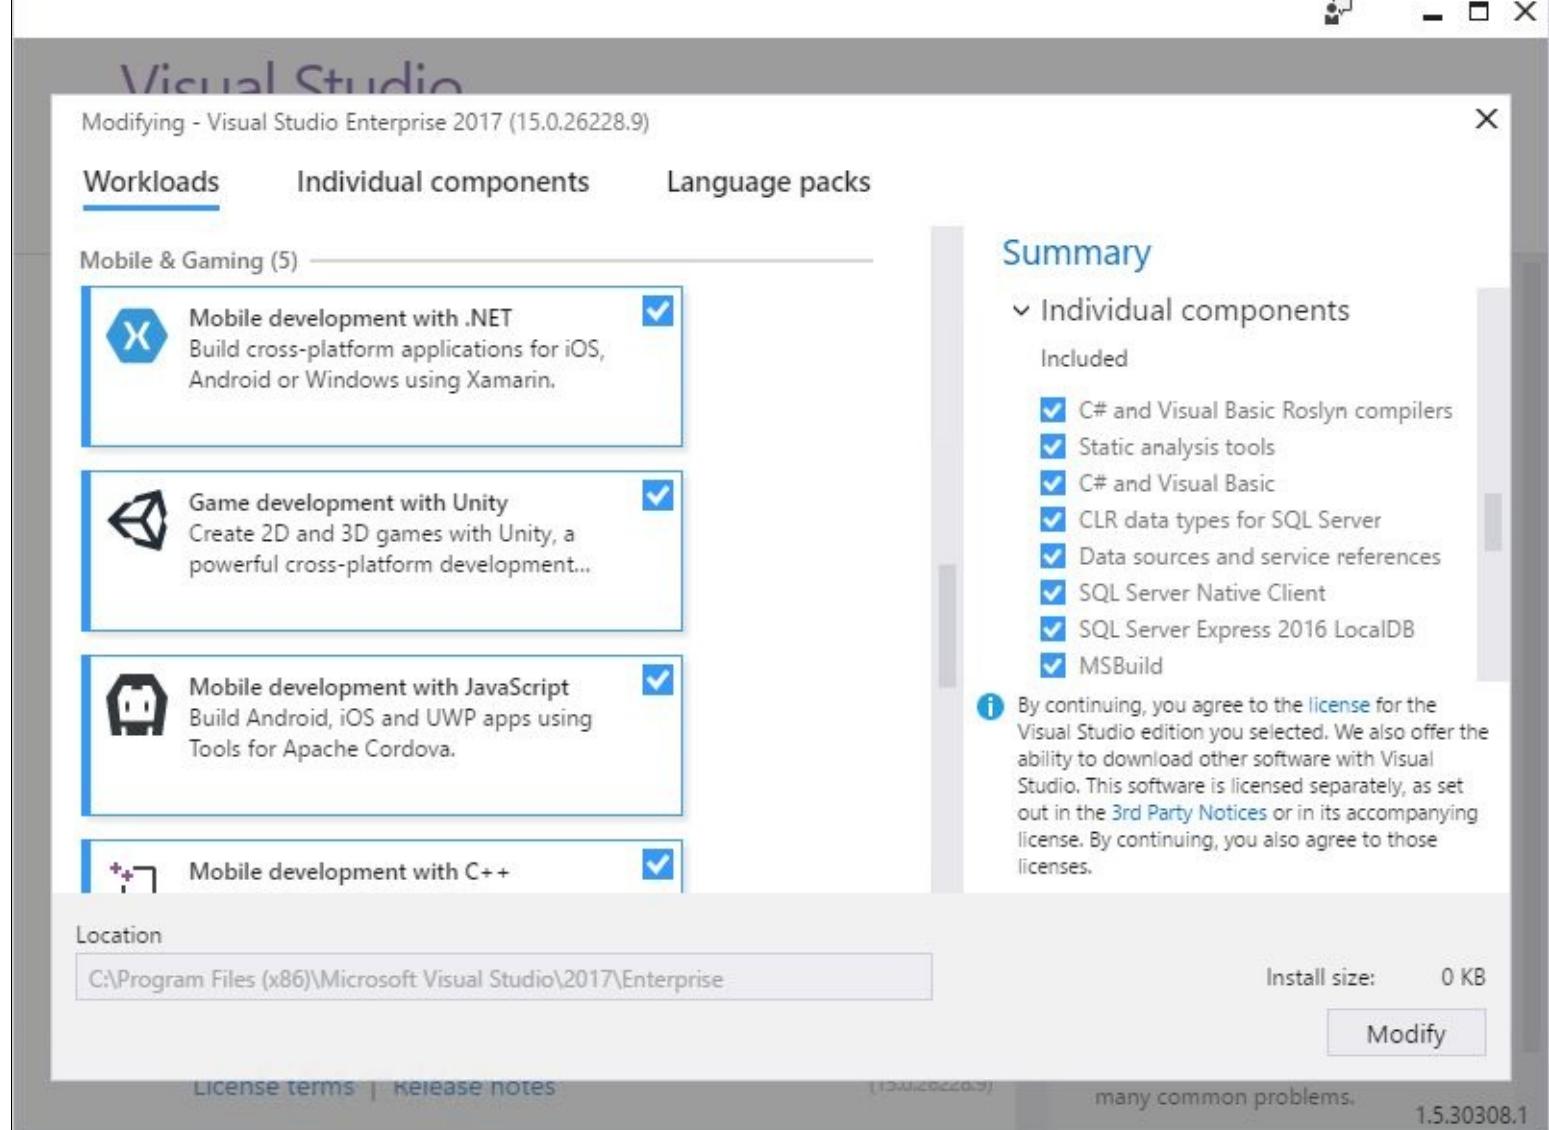

# How to do it...

1. Double-click on the installer you downloaded from the Visual Studio website. This will launch the installer and list the version of Visual Studio 2017 installed on your machine with a Modify button. Click on the Modify button:

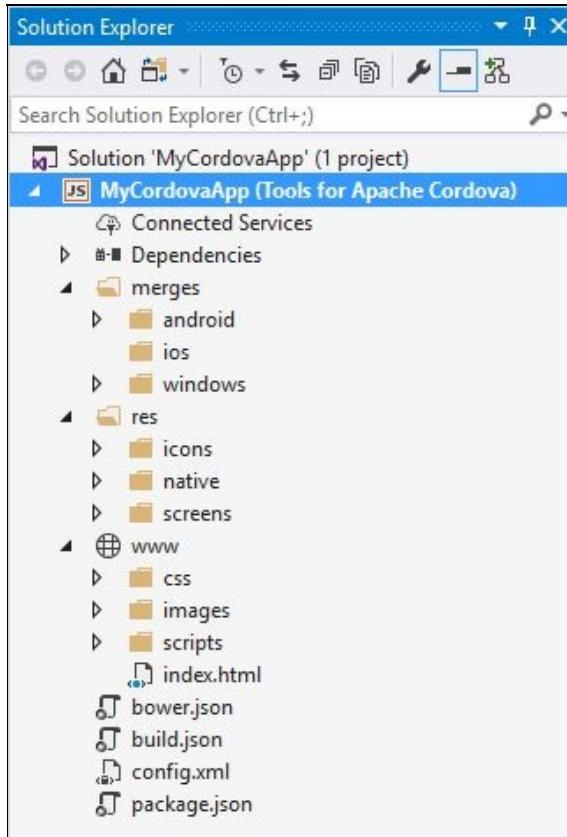

2. From the Mobile & Gaming group, select the Mobile development with JavaScript workload. Then, click on the Modify button. Depending on your specific requirements, additional components might be installed, such as support for the **Android SDK** and the **Google Android Emulator**:

3. Apache Cordova uses web technologies such as HTML, CSS, and JavaScript to build mobile applications that will run on Android, iOS and Windows devices. From Visual Studio, create a new application and select JavaScript from the Other Languages templates. Then select the Blank App (Apache Cordova) template. This is just a blank project that uses Apache Cordova to build a mobile app for Android, iOS, and **Universal Windows Platform (UWP)**. I just called my app MyCordovaApp.
4. Once Visual Studio has created your application, you will notice that it has a very specific folder structure:
  - **merges**: Expanding the `merges` folder, you will notice that you have three subfolders called `android`, `ios`, and `windows`. Developers can use these folders to deliver different content based on which mobile platform they are targeting.
  - **www**: This is where most of your development will take place. The `index.html` file will become the main entry point for your Cordova application. When your mobile application is started, Cordova will look for this index file and load that first. You will also notice subfolders under the `www` folder. Think of these as a regular web application folder structure, because that is exactly what they are. The `css` subfolder will contain any style sheets you need to use. Any images you need to use in your mobile application will be stored in the `images` subfolder. Lastly, you will add any JavaScript files used by your mobile (web) application in the `scripts` subfolder. If you expand the `scripts` subfolder, you will notice a JavaScript file called

`platformOverrides.js`. This is used in conjunction with the `merges` folder to deliver specific JavaScript code based on the mobile platform you are targeting.

- `res`: The `res` folder will be used to store non-web application resources that might be used by the different native mobile applications. These can be resources such as splash screens, images, icons, signing certificates, and so on:

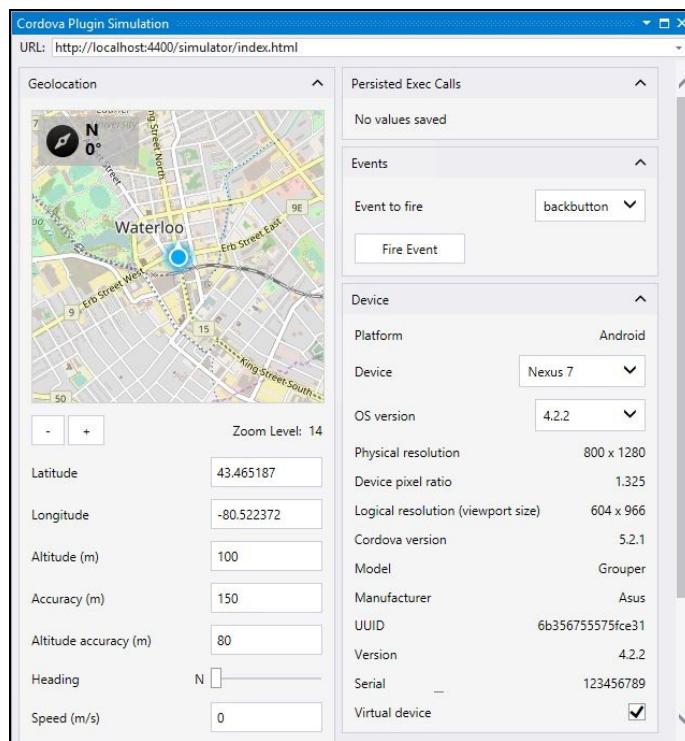

You will also notice several configuration files. These are `bower.json`, `build.json`, `config.xml`, and `package.json`. While I will not go into each one of these configuration files in detail, I want to briefly mention `config.xml` and `package.json` files. The `package.json` file is not currently used by Cordova at the time. It is intended to eventually replace the `config.xml` file. Currently, the `config.xml` file contains settings for your mobile application. Double-click on this file to view the custom editor for the Cordova application. The custom editor avoids the complexities of having to edit the XML file directly by providing a standard Windows form from where you can input the application-specific settings. Settings available to you as a developer are such settings as application name, author name, app description, device orientation, plugin configuration, and so on.

*It is imperative that you do not delete the `config.xml` file. Doing so will break your solution and the Cordova SDK will not be able to build and deploy your mobile application without it.*

5. At this point, you can select a device from the debug drop-down and run your mobile application. If you had to select Simulate in Browser - Nexus 7 (Tablet), Visual Studio will launch Google Chrome and display the default Cordova application. This is the default for every Cordova application and does not contain any functionality really. It merely lets you know that your Cordova application has started correctly. What is interesting though is that you will see a new tab open up in Visual Studio while your simulator is launched. It is called the Cordova Plugin Simulation and defaults to the Geolocation plugin. This allows developers to interact with plugins and fire specific events as your application runs.

application is running in the simulator. Any new plugins added to your Cordova application will expose additional panes in the Cordova Plugin Simulation:

6. Next, add the NuGet package `jQuery.mobile` to your solution. NuGet will install `jQuery.1.8.0` and `jquery.mobile.1.4.5` to your solution. At the time this book was written, it was advised that `jQuery.1.8.0` not be upgraded to the latest version due to compatibility reasons:

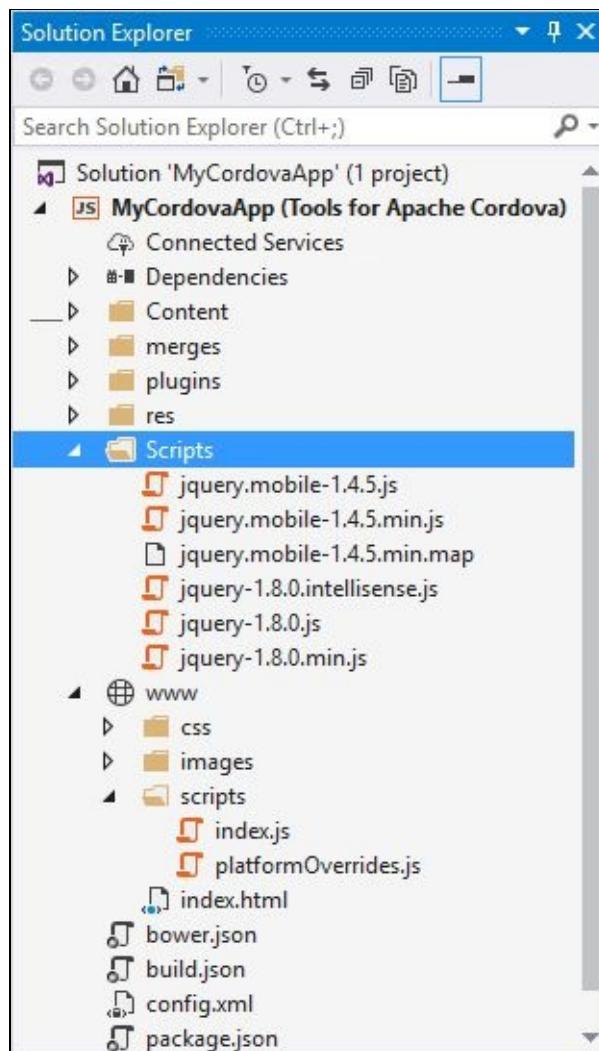

A screenshot of the NuGet Package Manager interface. The search bar at the top contains 'jquery.mobile'. On the left, there's a list of packages:

- jquery.mobile** by The jQuery Project, 907K downloads, v1.4.5. Description: A unified user interface system across all popular mobile device platforms, built on the rock-solid jQuery and jQuery UI foundation.
- jquery.mobile.rtl** by jQuery Foundation, Moutaz Shams, 2.69K downloads, v1.4.0. Description: Unofficial RTL version of jQuery Mobile for Right-To-Left websites such as Arabic, Persian, Urdu and Hebrew websites.
- jquery.mobile.mvc.dll** by Darren Horrocks, 1.81K downloads, v0.1.1. Description: Fluent implementation of ASP.NET-MVC HTML helpers for jQuery Mobile.
- jQuery.Mobile.Message** by John Rummell, 6.69K downloads, v1.10.4. Description: A simple jQuery plugin that uses jQuery Mobile themes to display info and error messages.

On the right, a sidebar titled 'Manage Packages for Solution' shows the selected package 'jquery.mobile'. It lists 'Version(s) - 0' and has checkboxes for 'Project' and 'MyCordovaApp', both of which are checked. At the bottom, there are buttons for 'Installed: not installed' and 'Uninstall' (disabled), and 'Version: Latest stable 1.4.5' with an 'Install' button.

7. In your solution, NuGet will add several JS files to your project's `scripts` folder. Drag all these JS

files to your `www/scripts` folder. Do the same with the project's `content` folder. Drag all the CSS files and the `images` subfolder to the `www/css` folder:

8. Swing back to and open your `index.html` file. You will see a section between the `<body></body>` tags that looks as follows:

```
<div class="app">
    <h1>Apache Cordova</h1>
    <div id="deviceready" class="blink">
        <p class="event listening">Connecting to Device</p>
        <p class="event received">Device is Ready</p>
    </div>
</div>
```

This is the default boilerplate code added by the template and we will not be using it. Replace this with the following code and also add `<script src="scripts/jquery-1.8.0.min.js"></script>` and `<script src="scripts/jquery.mobile-1.4.5.min.js"></script>` to the bottom of the body section where the other script references are.

 Note that your versions of the JS files might differ from the previously referenced versions.

When you are done, your `<body></body>` section should look as follows: `<body><div role="main" class="ui-content">`

```

<form>
<label id="current-date">The date is:</label>
<button id="get-date-btn" data-role="button"
data-icon="search">
Get Current Date</button>
</form>
</div>
<script src="scripts/jquery-1.8.0.min.js"></script>
<script src="scripts/jquery.mobile-1.4.5.min.js"></script>
<script src="cordova.js"></script>
<script type="text/javascript" src="cordova.js"></script>
<script type="text/javascript" src=
"scripts/platformOverrides.js"></script>
<script type="text/javascript" src="scripts/index.js"></script>
</body>

```

9. Then, between the `<head></head>` tags, add the `<link rel="stylesheet" href="css/jquery.mobile-1.4.5.min.css" />` style reference above the existing `<link rel="stylesheet" type="text/css" href="css/index.css">` reference.

*Note that your versions of the CSS files might differ from the versions referenced earlier.*

When you are done, your code should look similar to the following:

```

<!--
Meta references omitted for brevity
-->
<link href="css/jquery.mobile-1.4.5.min.css" rel="stylesheet" />
<link rel="stylesheet" type="text/css" href="css/index.css">
<title>MyCordovaApp</title>
</head>

```

10. Your application now includes the required jQuery libraries that will make your mobile application mobile and touch optimized. Your mobile application is now also responsive to the device it will be displayed on. We now need to add some basic styling to the application. Open up the `index.css` file referenced in the `<head></head>` section of your `index.html` file. This should be in `www/css/index.css`. Replace the contents with the following code. The `#get-date-btn` is just referencing the button on our form and setting the font size to 22 pixels. The `form` is styled to contain a solid border at the bottom of 1 pixel wide:

```

form {
    border-bottom: 1px solid #ddd;
    padding-bottom: 5px;
}

#get-date-btn {
    font-size: 22px;
}

```

11. We now need to add a click event for when the user taps on the Get Current Date button. To do this, open the `index.js` file located at `www/scripts/index.js`. Find the `onDeviceReady()` method and modify the code to look as follows:

```
function onDeviceReady() {
    // Handle the Cordova pause and resume events
    document.addEventListener( 'pause', onPause.bind(
        this ), false );
    document.addEventListener( 'resume', onResume.bind(
        this ), false );

    $('#get-date-btn').click(getCurrentDate);
};
```

12. Think of this code as an event handler for the `get-date-btn` button. It is actually adding a click listener to the button that will call the `getCurrentDate` function whenever the button is tapped by the user. It is probably a good time to mention the `(function () { ... })();` function that contains the `onDeviceReady()` function. This is called an **anonymous self-invoking function**, which is actually just something you can think of as a form load event. You will notice that it adds an event handler for the `onDeviceReady()` method.
13. Lastly, add the `getCurrentDate()` function to the `index.js` file.

*For the purposes of this recipe, I'll keep it simple and add the `getCurrentDate()` function to the `index.js` file because the code isn't really that complex. For more complex code, it would be better to create a separate JS file and reference that JS file in your `index.html` page (at the bottom of the `<body></body>` section) along with the other JS file references.*

The `getCurrentDate()` function is nothing special. It just gets the date and formats it to a `yyyy/MM/dd` format and displays it in the label on the `index.html` page. Your function should look as follows:

```
function getCurrentDate()
{
    var d = new Date();
    var day = d.getDate();
    var month = d.getMonth();
    var year = d.getFullYear();
    $('#current-date').text("The date is: " + year + "/"
+ month + "/" + day);
}
```

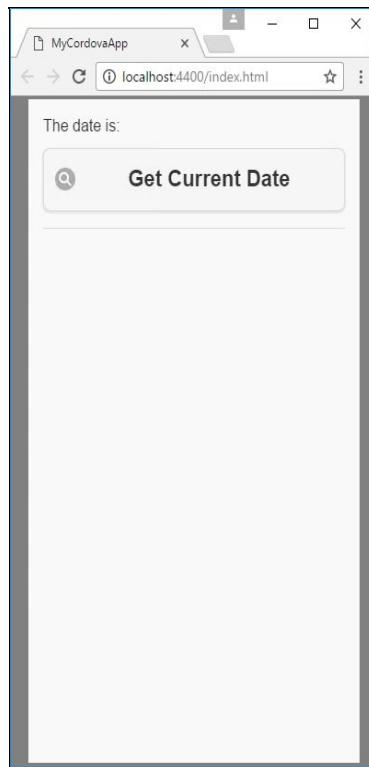

# How it works...

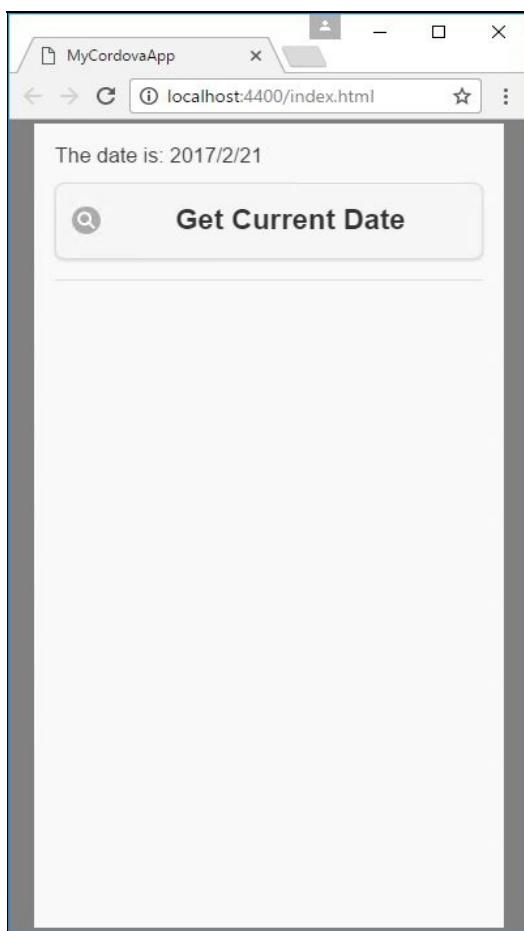

You can now start to debug your application. Let's choose a different simulator in Visual Studio. Select Simulate in Browser - LG G5 and press *F5*:

Chrome will launch and display your Cordova application:

Click on the Get Current Date button and the current date will be displayed above the button you just clicked on:

While your simulator is open, open the `index.js` file where you added the `getCurrentDate()` function and place a breakpoint on the line that reads `$('#current-date').text("The date is: " + year + "/" + month + "/" + day);`. Then click on the Get Current Date button again:

```
17
18     function getCurrentDate()
19     {
20         var d = new Date();
21         var day = d.getDate();
22         var month = d.getMonth();
23         var year = d.getFullYear();
24         $('#current-date').text("The date is: " + year + "/" + month + "/" + day);
25     }
}
```

You will notice that your breakpoint is hit and you can now step through your code inspecting variables and debugging your application just like you are used to doing. You can even set conditional breakpoints. This is simply fantastic.

There is so much more to learn surrounding developing applications using Cordova. Web developers will find this process familiar and should easily pick it up. You can now take this application and run it on any platform because it is completely cross-platform. What you can try next is running your Cordova application using one of the Android Emulators available. Play around with this example and add some more functional code. Think of accessing a web service to retrieve values or play around with the styles.

Being able to target different mobile devices from a single solution using Visual Studio allows developers the freedom to experiment and find what solution fits them and their development style the best. Cordova steps up to the plate and offers developers a fantastic solution for those that do not use

something such as Xamarin.

# Creating an iOS application using Xamarin.Forms and Visual Studio for Mac

Many developers want to try their hand at writing an iOS application. The big drawback has always been learning a new programming language and a new IDE. For some, it is probably not an issue as they want to learn something new. But for many .NET developers, being able to stick to an IDE and programming language they know is immensely empowering. Well, this is exactly what Xamarin.Forms and Visual Studio achieve.

*Please note that I am not including Xamarin.Android here as a consideration. I'm purely focusing on writing native iOS and Mac applications.*

Xamarin gives .NET developers the ability to use Visual Studio to write applications that can be run cross-platform easily, without having a separate code base for each. You therefore have a single code base for your application that will run on Windows, iOS/macOS, and Android. If you want to get into developing native iOS/macOS applications, you basically have (to my mind anyway) four viable options. They are as follows:

- Buy yourself a Mac and teach yourself Xcode, Swift, and/or Objective-C.
- Buy yourself a Mac and install Parallels, where you can install Windows, Visual Studio, and other Windows-based software (Mac is not exclusively used for development). You can see a video on the **Developer Community** YouTube channel I created a few years back (<https://www.youtube.com/developercommunity>). In that video, I show you how to install Visual Studio 2013 on a Mac using Parallels.
- Buy yourself a Mac and download **Visual Studio for Mac** (currently still in preview at the time of writing) and install that on your Mac (Mac is exclusively used for developing Android and iOS/macOS applications).
- Buy yourself a Mac and use that to compile iOS/macOS applications developed on your Windows PC running Visual Studio. Do this if you need to create applications that can still target Windows-based platforms in addition to Android and iOS/macOS.

*If you are going to be using **Visual Studio for Mac** and Xamarin.Forms, then you will not be able to create Xamarin.Forms projects for Windows and Windows phone because these cannot be build on macOS. Also note that I didn't consider MacinCloud here because somewhere along the development process, I believe that it is really beneficial to own a physical Apple Mac device.*

From the points listed earlier, it is clear that you are going to need a Mac. While it is entirely possible to have Visual Studio installed on your Windows PC and connect to the Xamarin Mac agent when the machines are on the same local network, it does become a bit of an inconvenience when you need to try and remotely access the Mac (from your work office, for example). While theoretically this should be possible, you need to do some legwork to make this all work. For one, you will probably need to add some sort of port forwarding on your router to allow remote connections to your Mac. You will also need to assign your Mac a static IP address (or even buy a static IP address for your router) so that if a restart

happens due to a power failure when you are working remotely, you will still be able to access your Mac for your Visual Studio builds.

Installing Parallels on your Mac is great, and will really come in handy when you have other Windows-based software that you want to use on your Mac. If you (like me) use your Mac exclusively for development purposes, then Parallels might not be a viable solution. This leaves **Visual Studio for Mac** and is a great option if you only plan to develop iOS/macOS and Android applications.

To download Visual Studio for Mac, head on over to <https://developer.xamarin.com/visual-studio-mac/> and click on the download link. The installation process is somewhat similar to the installation process in the first recipe of this chapter. The difference here is that the actual Visual Studio application will be installed on the Mac and not on a Windows PC on the same network.

# Getting ready

After downloading Visual Studio for Mac, start the installation process. This is very similar to the process outlined in the first recipe. It can take a while to complete, so once again, go get yourself a cup of coffee. Creating applications with Visual Studio for Mac is a familiar experience for .NET developers coming from Visual Studio for Windows.

At the heart of Visual Studio for Mac is the Roslyn compiler that is used for refactoring and IntelliSense. The build engine is MSBuild and the debugger engine is the same for Xamarin and .NET Core applications. The software requirements for Xamarin development and Visual Studio for Mac are as follows:

- You will need a Mac running OS X El Capitan (10.11) or macOS Sierra.
- The iOS 10 SDK that ships with Xcode 8 is required. Xcode can be downloaded for free as long as you have a valid iTunes account.
- Visual Studio for Mac requires .NET Core which can be downloaded by following the steps outlined at <https://www.microsoft.com/net/core#macos>. You must complete all the steps listed to ensure that .NET Core is installed correctly. While you are there, make a note to watch a few of Kendra Havens' Channel 9 videos on getting started with .NET Core, at <https://channel9.msdn.com/>. While you are at it, have a look at the other brilliant content on Channel 9.
- If you plan to submit your applications to the Apple App Store, then you will need to purchase a developer license, which is currently priced at \$99/year. You can, however, develop your applications without purchasing a developer license.

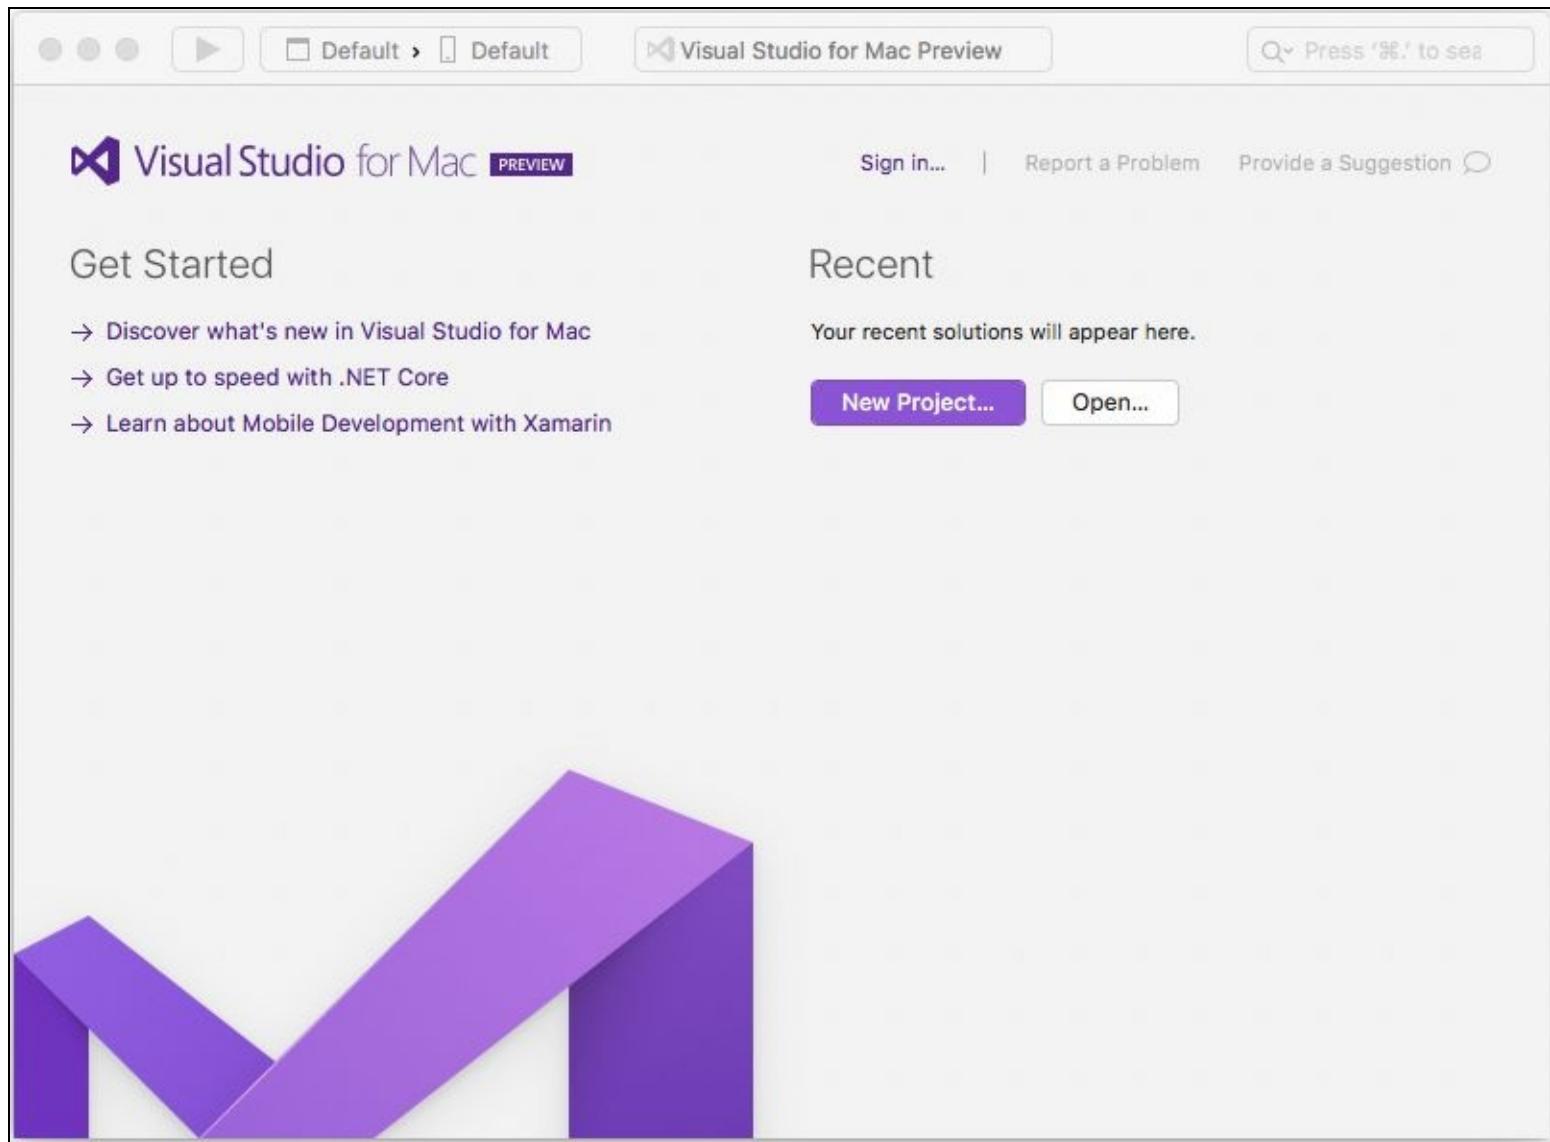

*Note that if you plan to install Visual Studio for Mac alongside Xamarin Studio, then you need to be aware that Visual Studio for Mac requires Mono 4.8. Installing Xamarin Studio will downgrade Mono to an older version. To get around this, you need to opt out of the Mono 4.6 selection during the Xamarin Studio update screen.*

With this rather detailed checklist of requirements out of the way, let's get ready to create an iOS application.

# How to do it...

1. Launch Visual Studio for Mac and sign in with your Microsoft Account details. You will notice the Get Started section that lists a number of useful articles that help developers get up and running with Visual Studio for Mac:

2. Next, click on New Project... and select the Forms App project from the Xamarin.Forms group in the Multiplatform App templates. Then, click on Next:

## Choose a template for your new project

 Multiplatform App Library Tests iOS App Library Tests tvOS App Library Android App Library Tests Mac App Library .NET Core

## Xamarin.Forms

 Forms App

C#

 Blank Forms App

## Native (iOS, Android)

 Native App (iOS, Android) Blank Native App (iOS, Android)

## Games (iOS, Mac)

 SpriteKit Game SceneKit Game**Forms App**

Creates a Xamarin.Forms and a corresponding ASP.NET Core Web API backend.

 Cancel Previous Next

3. We then need to give our application a name and an Organization Identifier. I simply called my app HelloWorld and then selected only iOS under Target Platforms. Click on Next to continue:

## Configure your Forms App

App Name: Organization Identifier:  i

- com.csharpcookbook.helloworld
- com.csharpcookbook.helloworld

Target Platforms:  Android iOS[Cancel](#)[Previous](#)[Next](#)

4. Lastly, decide whether you want to configure your project to use Git for version control and Xamarin Test Cloud. When you have configured what you need to, click on Create:

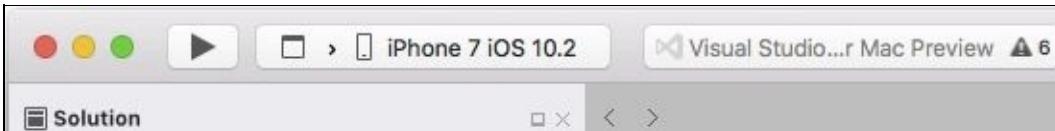

## Configure your new Forms App

Project Name: Solution Name: Location:   Create a project directory within the solution directory.Version Control:  Use git for version control. Create a .gitignore file to ignore inessential files.Xamarin Test Cloud:  Add an automated UI test project. [Learn More](#)

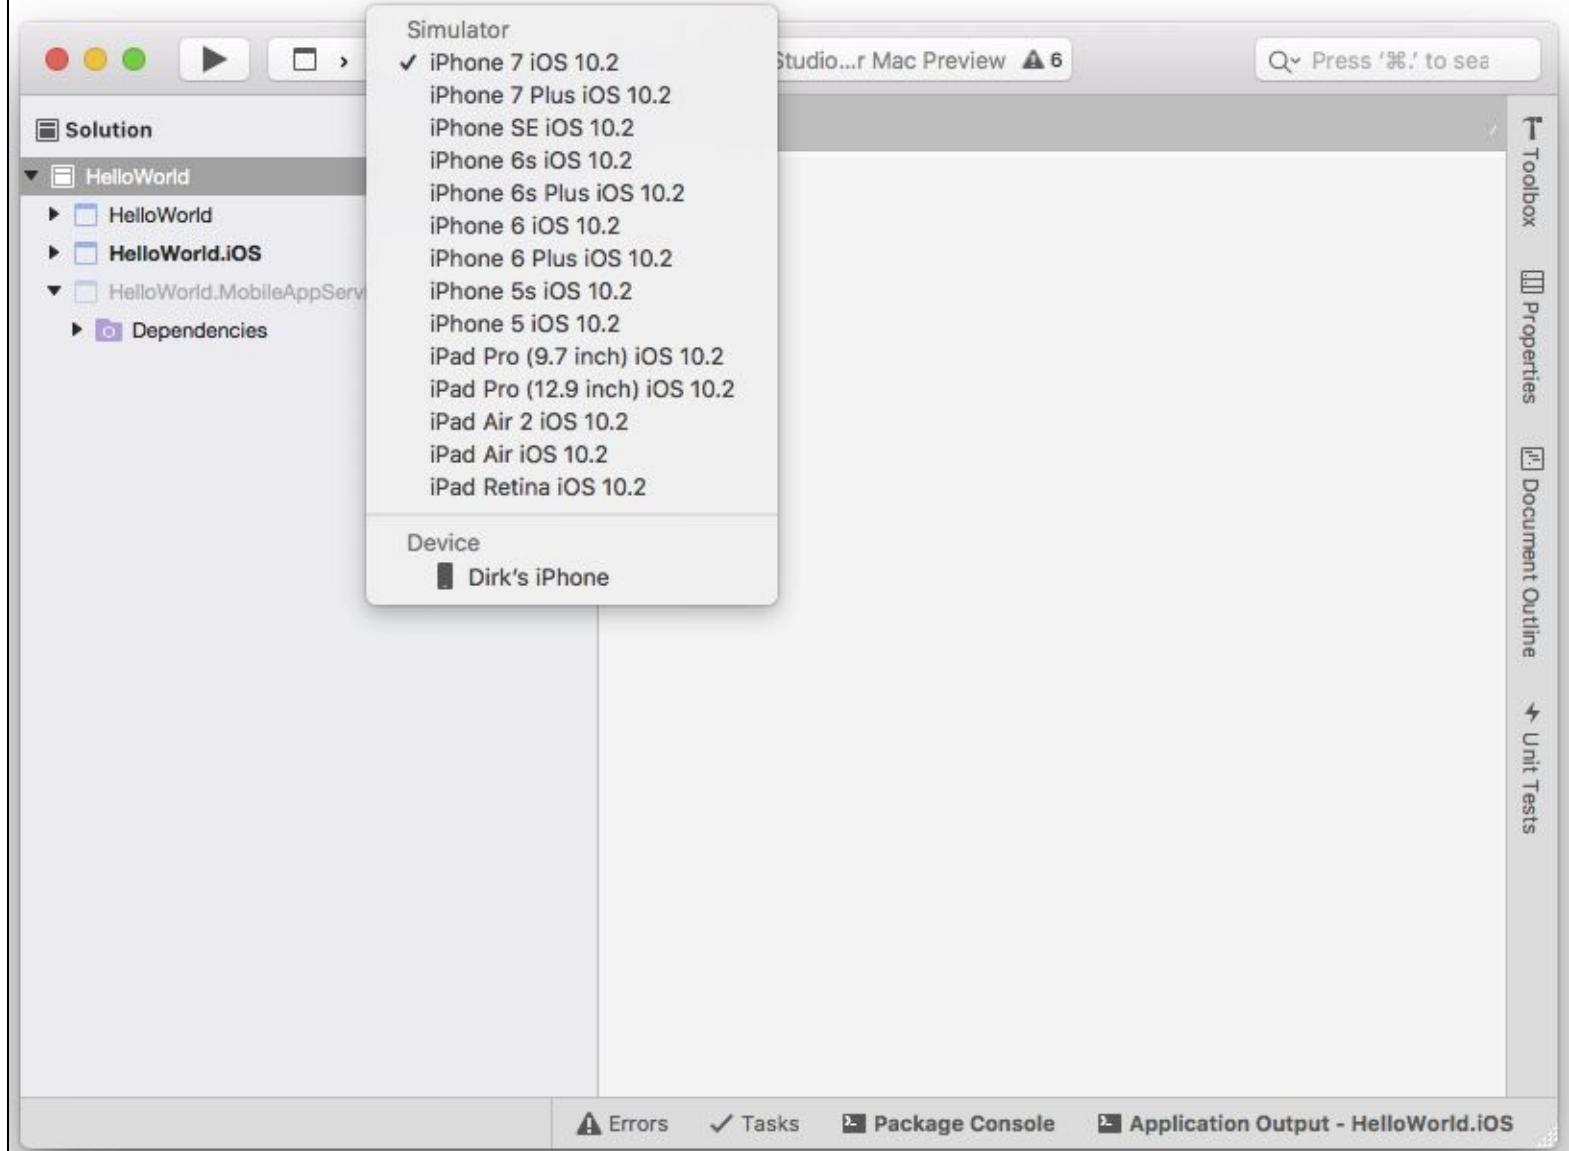

## PREVIEW

- /Users/dirkstrauss/Projects
- HelloWorld
- HelloWorld.sln
- HelloWorld
- HelloWorld.csproj

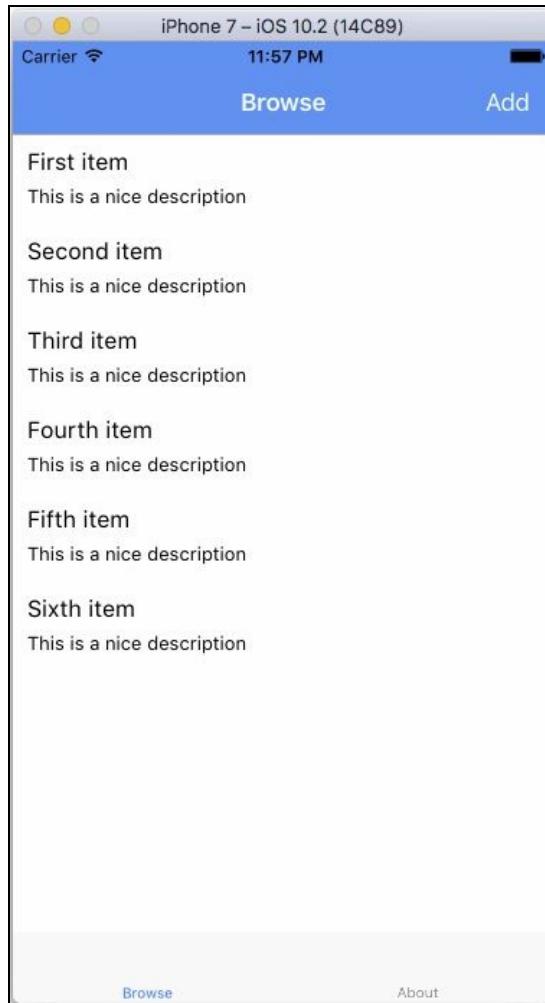

- When your project is created, you will notice that you can select the device you want to simulate by clicking on the down arrow next to the Debug button:

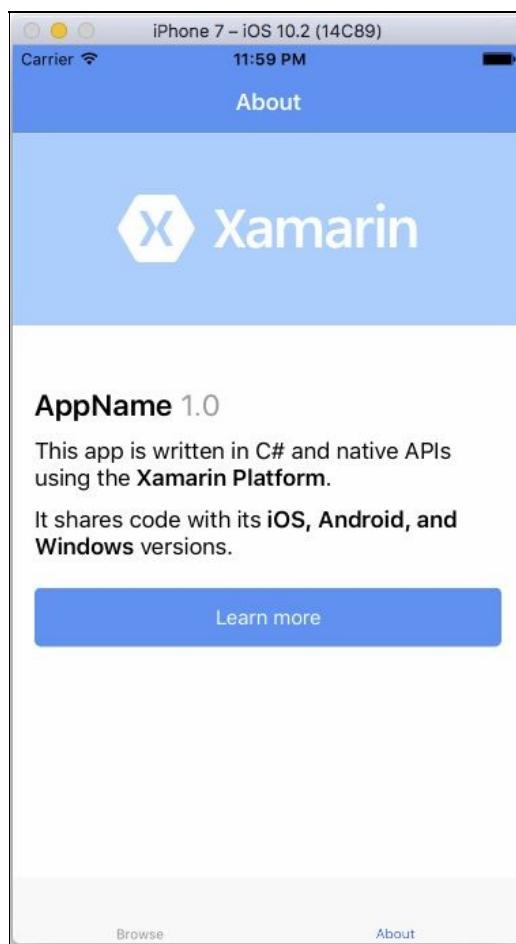

- This will list the different simulators available to you, as well as any devices tethered to your Mac (in this case, my iPhone):

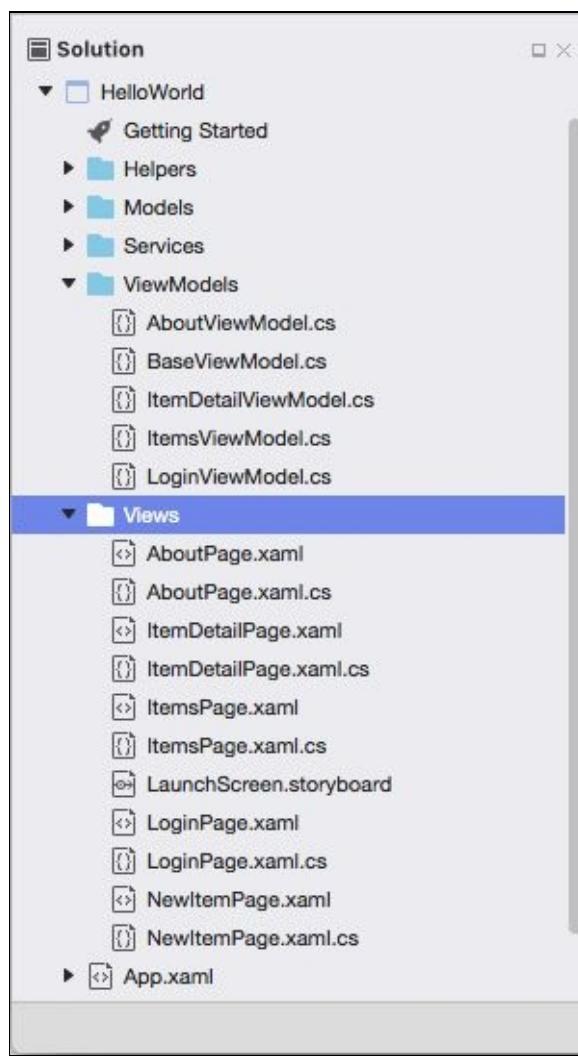

7. Clicking on the Run button will launch the simulator for the selected device and display the default application created for you when you created the Xamarin.Forms iOS application:

8. The application in the simulator is fully functional and you can interact with it to get a feel for how the simulator works. As mentioned earlier, if you have an iOS device tethered to your Mac, you can even launch the application on your device to test it. Clicking on the About tab, for example, will display the About page:

9. Click on the Stop button in Visual Studio for Mac and go back to your solution. Expand the `ViewModels` and `Views` folders. You will see a very familiar structure:

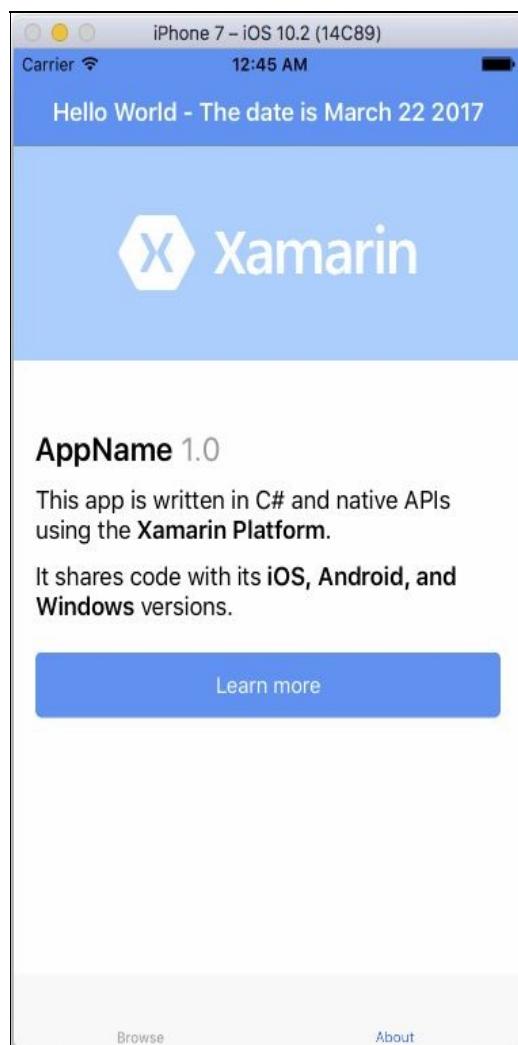

10. In the `ViewModels` folder, open the `AboutViewModel.cs` file. In the constructor `AboutViewModel()`, you will see the following code:

```
public AboutViewModel()
{
    Title = "About";
    OpenWebCommand = new Command(() => Device.OpenUri(new
        Uri("https://xamarin.com/platform")));
}
```

11. For now, just to illustrate the use of C#, change the code here to look like the following code listing. Do you notice the first line of code? The section after `var titleText =` is an interpolated string  `$"Hello World - The date is {DateTime.Now.ToString("MMMM dd yyyy")}"`. Interpolated strings were introduced in C# 6.0. Click on the Play button to launch the application in the simulator:

```
public AboutViewModel()
{
    var titleText = $"Hello World - The date is {
        DateTime.Now.ToString("MMMM dd yyyy")}";
    Title = titleText;
    OpenWebCommand = new Command(() => Device.OpenUri(new
        Uri("https://xamarin.com/platform")));
}
```

12. Now, click on the About tab again and look at the title. The title has changed to display Hello World and the current date:

# How it works...

Well, I will be the first to admit that the code we wrote was not earth-shattering at all. In fact, we basically piggybacked on an existing application and just modified a little bit of code to display Hello World and the current date. One thing that you need to remember here though is that we have written C# code and compiled that to a native iOS application.

There is still much to learn. We have not even scratched the surface with what is available now with Visual Studio for Mac, Xamarin.Forms and cross-platform C# applications. Xamarin has really good documentation that will assist you as you navigate the new causeways of developing applications using Xamarin. A nice case study to read through is the Tasky case study, which can be found at [https://developer.xamarin.com/guides/cross-platform/application\\_fundamentals/building\\_cross\\_platform\\_applications/case\\_study-tasky/](https://developer.xamarin.com/guides/cross-platform/application_fundamentals/building_cross_platform_applications/case_study-tasky/). This will give you a good idea about what is involved with developing a cross-platform application using Xamarin.

Why don't you try to play around a bit more with the application we just created? See what is possible and what differences there are in approaching database logic and reading user input, for example. Visual Studio for Mac has opened a new world for developers, making it easier than ever to get started developing native iOS applications.

# Writing Secure Code and Debugging in Visual Studio

In this chapter, we will take a look at some examples of being more efficient as a developer when it comes to debugging your code. We will also be looking at how to write secure code. Writing secure code can be a challenge, but consider the following: if part of your code security involves making sure that passwords are securely stored, why write that code over and over between projects? Write the code once and implement it in every new project you create. The concepts we will be looking at are as follows:

- Encrypting and storing passwords correctly
- Using `SecureString` in code
- Securing sensitive parts of the `App.config/web.config`
- Preventing SQL injection attacks
- Using IntelliTrace, diagnostic tools, and historical debugging
- Setting conditional breakpoints
- Using PerfTips to identify bottlenecks in code

# Introduction

Something that many developers tend to miss is the need to write secure code. Development deadlines and other project-related pressures cause developers to put delivering code above doing it the right way. Many of you might not agree with me, but believe me when I say that I have heard the excuse of, "We do not have the budget for this," one too many times. This is usually when the development budget has been determined by other stakeholders and the developer not consulted.

Consider a situation where a consultant tells the developer that they have sold a system to a customer. That system now needs to be developed. Furthermore, the developer is told that they have  $x$  amount of hours to complete the development. A document outlining the requirements is given to the developer and the developer is given the go-ahead to begin, and to complete development in the required time.

This scenario is the reality many developers face. You might think that this scenario can't possibly exist, or perhaps you are reading this and relate to the scenario as being how the process currently works in your company. Whatever the case may be, this is something that happens today in software development.

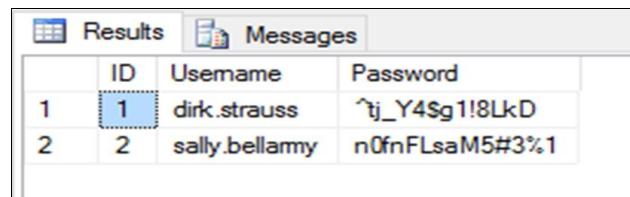

So, how do developers combat project suicide (I call these projects this because projects approached like this rarely succeed)? Start by creating reusable code. Think of processes you repeat often enough to warrant writing a reusable DLL for. Did you know that you can create Visual Studio templates? If you have a standard project structure you use, create a template from it and reuse it for each new project, thereby speeding up delivery and cutting down on bugs.

A few considerations for project templates are database layers, security layers, common validation code (does this data table contain any data?), common extension methods, and so on.

# Encrypting and storing passwords correctly

One thing I have often seen is badly stored passwords. Just because the password is stored in a database on your server, does not make it secure. So, what do badly stored passwords look like?

A screenshot of a database management system's results window. The window has tabs for 'Results' and 'Messages', with 'Results' selected. There is a header row with columns labeled 'ID', 'Username', and 'Password'. Below the header are two data rows. The first row contains ID 1, Username 'dirk.strauss', and Password '^tj\_Y4\$g1!8LkD'. The second row contains ID 2, Username 'sally.bellamy', and Password 'n0fnFLsaM5#3%1'. The 'ID' column is highlighted with a blue selection box.

ID	Username	Password
1	dirk.strauss	^tj_Y4\$g1!8LkD
2	sally.bellamy	n0fnFLsaM5#3%1

Secure passwords stored badly are no longer secure. The passwords in the previous screenshot are the actual user passwords. Entering the first password, `^tj_Y4$g1!8LkD` at the login screen will give the user access to the system. Passwords should be stored securely in the database. In fact, you need to employ salted password hashing. You should be able to encrypt the user's password, but never decrypt it.

So, how do you decrypt the password to match it to the password the user enters on the login screen? Well, you don't. You always hash the password the user enters at the login screen. If it matches the hash of their real password stored in the database, you give them access to the system.

# Getting ready

The SQL tables in this recipe are for illustration only and are not written by the code in the recipe. The database can be found in the `_database scripts` folder that accompanies the source code for this book.

```
namespace Chapter15 {  
    public static class Recipes {  
        public static string saltValue { get; set; }  
        public static string hashValue { get; set; }  
    }  
}
```

using System.Security.Cryptography;

```
public static class Recipes {  
    public static string saltValue { get; set; }  
    public static string hashValue { get; set; }  
    public static void RegisterUser(string password, string username)  
    {  
        public static void ValidateLogin(string password, string username)  
    }  
}
```

```
public static void RegisterUser(string password, string username) {  
    // Create a truly random salt using RNGCryptoServiceProvider.  
    RNGCryptoServiceProvider csprng = new RNGCryptoServiceProvider();  
    byte[] salt = new byte[32];  
    csprng.GetBytes(salt);  
    // Get the salt value  
    saltValue = Convert.ToBase64String(salt);  
    // Salt the password  
    byte[] saltedPassword = Encoding.UTF8.GetBytes(saltValue + password);  
    // Hash the salted password using SHA256  
    SHA256Managed hashstring = new SHA256Managed();  
    byte[] hash = hashstring.ComputeHash(saltedPassword);  
    // Save both the salt and the hash in the user's database record.  
    saltValue = Convert.ToBase64String(salt);  
    hashValue = Convert.ToBase64String(hash);  
}  
}
```

```
public static void ValidateLogin(string password, string username) {  
    // Read the user's salt value from the database  
    string saltValueFromDB = saltValue;  
    // Read the user's hash value from the database  
    string hashValueFromDB = hashValue;  
    byte[] saltedPassword = Encoding.UTF8.GetBytes(saltValueFromDB + password);  
    // Hash the salted password using SHA256  
    SHA256Managed hashstring = new SHA256Managed();  
    byte[] hash = hashstring.ComputeHash(saltedPassword);  
    string hashToCompare = Convert.ToBase64String(hash);  
    if (hashValueFromDB.Equals(hashToCompare))  
        Console.WriteLine("User Validated.");  
    else  
        Console.WriteLine("Login credentials incorrect. User not validated.");  
}  
}
```

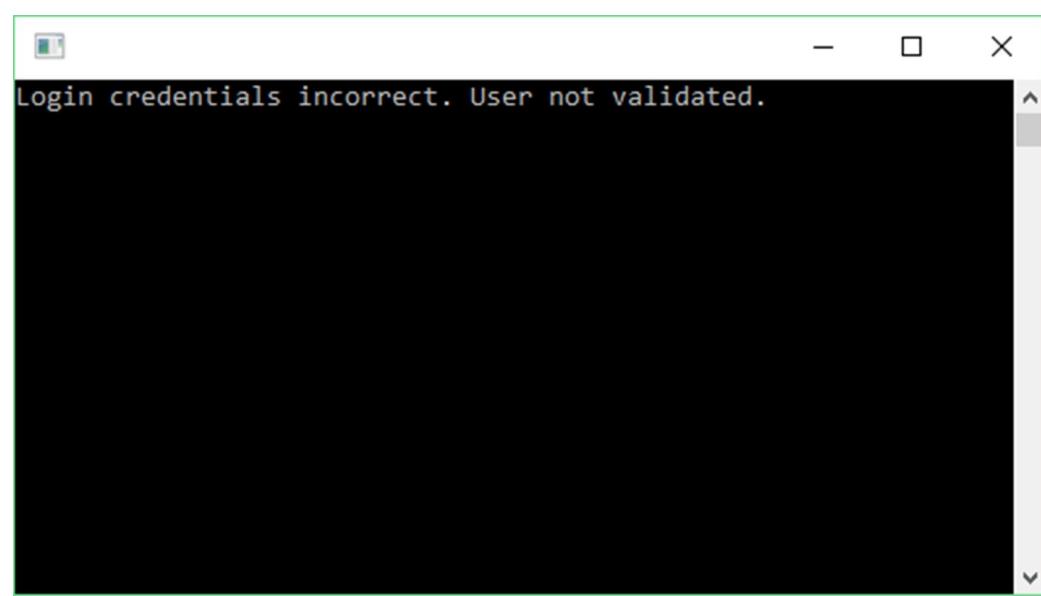

using static Chapter15.Recipes;

```
string username = "dirk.strauss";  
string password = "^tj_Y4$g1!8LkD";  
RegisterUser(password, username);  
ValidateLogin(password, username);  
Console.ReadLine();
```

```
string username = "dirk.strauss";  
string password = "^tj_Y4$g1!8LkD";  
Console.ReadLine();
```

```
RegisterUser(password, username); <br/><br/> password = "WrongPassword"; <br/>  
ValidateLogin(password, username); <br/> Console.ReadLine();
```

16. When you debug the application, you will see that the user is not validated:

# How it works...

Nowhere in the code did we decrypt the password. In fact, the password is never stored anywhere. We always worked with the hash of the password. Here are the important points to take away from this recipe:

- Never use the `Random` class in C# to generate your salt. Always use the `RNGCryptoServiceProvider` class.
- Never reuse the same salt in your code. So don't create a constant with your salt and use it to salt all the passwords in your system.
- Never tell the user that the password is incorrect if the password didn't match. Also, never tell the user that they entered an incorrect username. This prevents someone trying to compromise the system after discovering that they got one of the two login credentials correct. Rather, if either the username or password has been entered incorrectly, notify the user that their login credentials are incorrect. This could mean that either the username or password (or both) has been entered incorrectly.
- You can't get the passwords from the hash or salt stored in the database. Therefore, if the database was compromised, the password data stored within it would not be at risk. The encryption of the user's password is a one-way operation, meaning that it can never be decrypted. Also important to note is that, even if the source code was compromised and stolen by someone with malicious intent, you would not be able to use the code to decipher the encrypted data in the database.
- Combine the previous methods with a strong password policy (because even in 2016, there are still users that think using '`13tm31n`' for a password is good enough), and you have a very good password encryption routine.

When we look at the user access table, the correct way to store user credentials would look something like this:

	ID	Username	Salt	Hash
1	1	dirk.strauss	KxZH/jO8OFbNBvAiUJDnTHwG6MJ384+Tlq1JbKnKYY=	Togax/Wlna6Y8wblyiSvX7GFIQBf4MQ+foBfobSILzo=
2	2	sally.bellamy	9qSLUCH+VLQYa5DlwIclpQoadyiVKlxqqsuabN3k0=	vOBzPiM2Z+qxed7n8gVKGfnm3o6lvqXIRkrWR2hM9k=

The salt and hash are stored alongside the username, and are secure because they can't be decrypted to expose the actual password.

*If you sign up for a service on the Internet and they send you a confirmation either via e-mail or text message and display your password in this message in plain text, then you should seriously consider closing your account. If a system can read your password and send it to you in plain text, so can anybody else. Never use the same password for all your logins.*

# Using `SecureString` in code

Securing your application against malicious attacks is not an easy task. It is the constant struggle between writing secure code while minimizing bugs (which hackers usually exploit) and black hats writing more and more sophisticated methods to compromise systems and networks. I personally believe that higher learning institutions need to teach IT students two things:

- How to use and integrate with a popular ERP system
- Proper software security principles

In fact, I believe that secure programming 101 must not simply be a module or topic in a given IT course, but a whole course on its own. It needs to be handled with the seriousness and respect it deserves and needs to preferably be taught by someone who can actually hack a system or network.

White hats teaching students how to compromise systems, exploit vulnerable code, and infiltrate networks will make a big difference in changing the way future software developers approach programming. It comes down to developers knowing what not to do when programming defensively. It is quite possible that some of those students might go on to become black hats themselves, but they would have done that irrespective of whether they took a class on hacking secure programming or not.

# Getting ready

The code might look a little funny in some places. This is because `SecureString` is using unmanaged memory to store the sensitive information. Rest assured that `SecureString` is well supported and used within the .NET Framework, as can be seen from the instantiation of the `SqlCredential` object used in creating

```
SqlCredential cred = new SqlCredential()
```

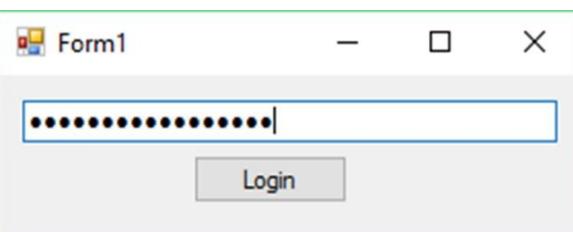

`SqlCredential(string userId, SecureString password)`

Creates an object of type `SqlCredential`.  
`userId`: The user id.

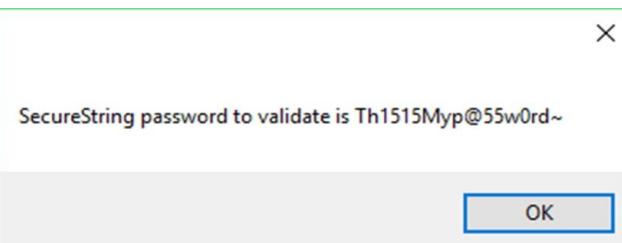

connections to a database:

```
private void textBox1_KeyPress(object sender, KeyPressEventArgs e) {  
}  
}  
  
using System.Runtime.InteropServices;  
  
SecureString secure = new SecureString();  
  
private void textBox1_KeyPress(object sender, KeyPressEventArgs e) {  
}  
secure.AppendChar(e.KeyChar);  
}  
  
private void btnLogin_Click(object sender, EventArgs e) {  
    IntPtr unmanagedPtr = IntPtr.Zero;  
    try {  
        if (secure == null)  
            throw new ArgumentNullException("Password not defined");  
        unmanagedPtr = Marshal.SecureStringToGlobalAllocUnicode(secure);  
        MessageBox.Show($"SecureString password to validate is  
{Marshal.PtrToStringUni(unmanagedPtr)}");  
    } catch (Exception ex) {  
        MessageBox.Show(ex.Message);  
    } finally {  
        Marshal.ZeroFreeGlobalAllocUnicode(unmanagedPtr);  
        secure.Dispose();  
    }  
}
```

11. Run your Windows forms application and type in a password:

12. Then click on the Login button. You will then see the password you typed in displayed in the message box:

# How it works...

It has become almost a habit for many developers to use `System.String` to store sensitive information such as passwords. The problem with this approach is that `System.String` is immutable. This means that the object created in memory by `System.String` can't be changed. If you modify the variable, a new object is created in memory. You also cannot determine when the object created by `System.String` will be removed from memory during garbage collection. Conversely, using the `SecureString` object, you will encrypt sensitive information and, when that object is no longer needed, it is deleted from memory. `SecureString` encrypts and decrypts your sensitive data in unmanaged memory.

Now, I need to be clear regarding one thing here. `SecureString` is by no means foolproof. If your system contains a virus with the sole purpose of compromising the `SecureString` operations, using it doesn't help much (be sure to use proper anti-virus software anyway). At some point during the code execution, the string representation of your password (or sensitive information) is visible. Secondly, if a hacker somehow found a way to inspect your heap or log your key strokes, the password might be visible. The use of `SecureString`, however, makes this window of opportunity for a hacker much smaller. The window of opportunity reduces because there are less attack vectors (points of entry for a hacker) thereby reducing your attack surface (sum of all points of attack by a hacker).

The bottom line is this: `SecureString` is there for a reason. As a software developer concerned about security, you should be using `SecureString`.

# Securing sensitive parts of the App.config/web.config

As a developer, you will undoubtedly work with sensitive information such as passwords. How you handle this information during development is very important. In the past, I have received copies of a client's live database to use for testing. This does pose a very real security risk for your client.

Often, we keep settings in a `web.config` file (when working with web applications). For this example, though, I will be demonstrating a console application that uses an `App.config` file. The same logic can be applied to a `web.config` file too.

# Getting ready

Creating a console application is the quickest way to demonstrate this recipe. If, however, you want to follow along using a web application (and securing a `web.config` file), you can do so.

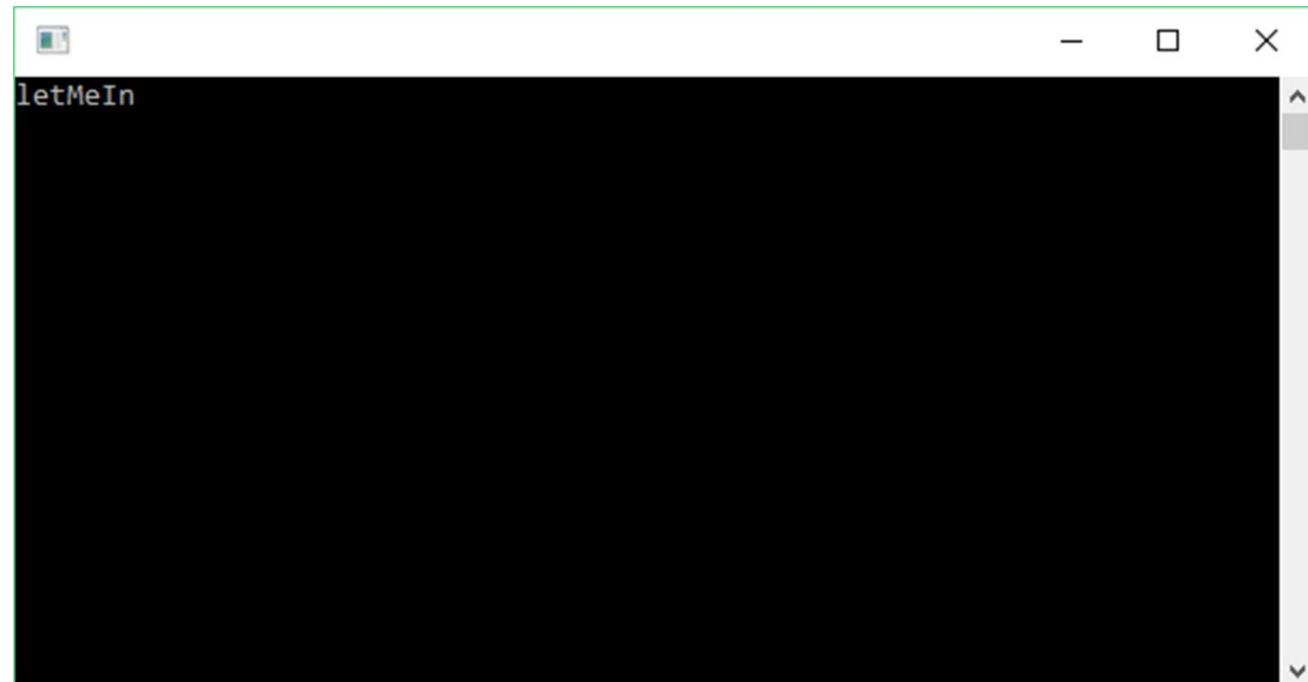

```
<?xml version="1.0" encoding="utf-8"?> <br/> <configuration> <br/> <startup> <br/> <supportedRuntime version="v4.0" sku=".NETFramework,<br/> Version=v4.6.1"/> <br/> </startup> <br/> <appSettings> <br/> <add key="name" value="Dirk"/> <br/> <add key="lastname" value="Strauss"/> <br/> <add key="Secret" value="letMeIn"/> <br/> </appSettings> <br/> </configuration>
```

```
<appSettings file="C:\temp\secret\secret.config">:
```

```
using System.Configuration;
```

```
string sSecret = ConfigurationManager.AppSettings["Secret"]; <br/> Console.WriteLine(sSecret); <br/> Console.ReadLine();
```

12. Run your console application, and you will see that the sensitive data has been read from the secret .config file, which was merged with the App .config file at runtime:

# How it works...

Something I need to point out here is that this technique will also work for `web.config` files. If you need to remove sensitive information from your configuration file, move it to another file so that it doesn't get included in your source control check-in or deployment.

# Preventing SQL injection attacks

SQL injection attacks are a very real problem. There are too many applications that still make themselves vulnerable to this kind of attack. If you develop a web application or website, you should be vigilant about bad database operations. Vulnerable in-line SQL exposes the database to a SQL injection attack. A SQL injection attack is where an attacker modifies SQL statements via a web form input box to produce a different result than originally intended. This is usually attempted on a form where the web application is supposed to access the database to authenticate the user login. By not sanitizing the user input, you are exposing your data to exploits such as this.

The accepted solution to mitigate SQL injection attacks is to create a parameterized stored procedure, and call that from your code.

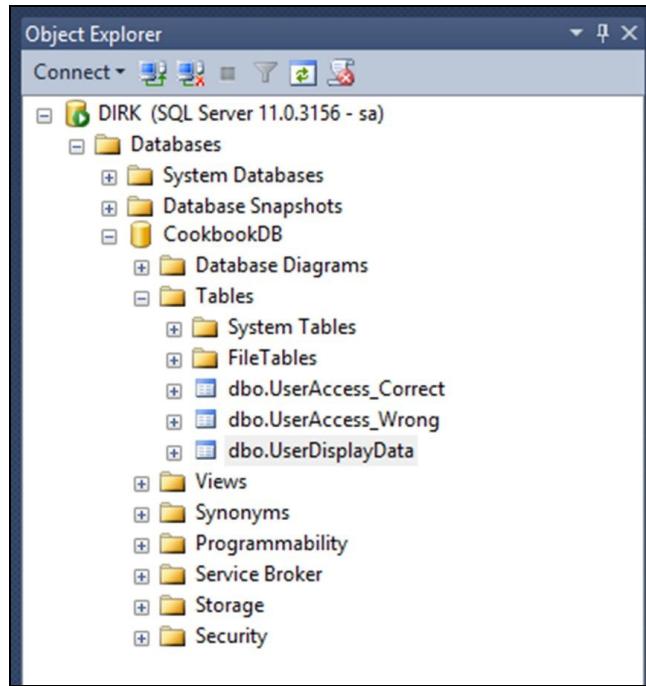

# Getting ready

You need to create the `cookbookDB` database in your SQL Server before continuing this recipe. You will find the script in the `_database scripts` folder in the accompanying source code.

# How to do it...

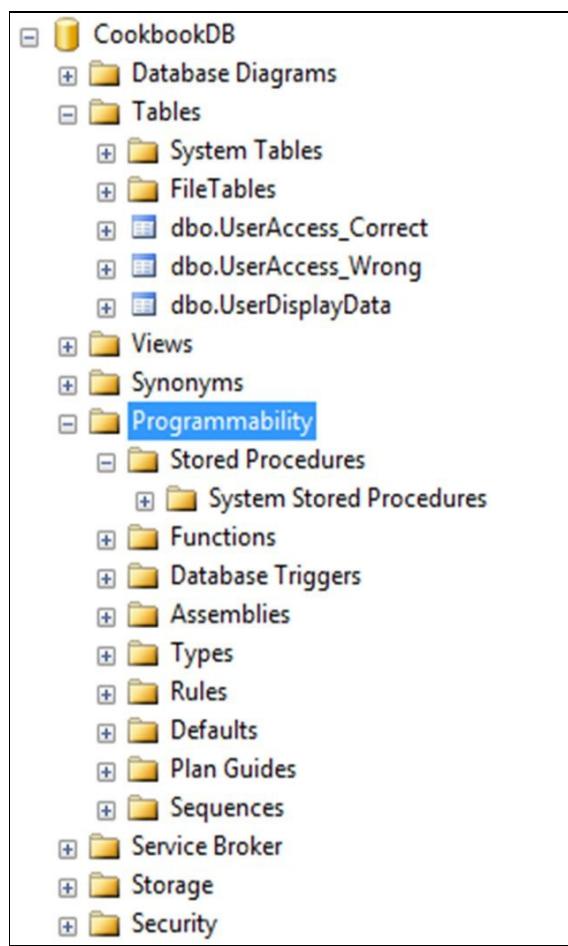

1. For this recipe, I am using SQL Server 2012. The concept is the same if you are using an older version of SQL Server. After you have created the `CookbookDB` database, you will see that there is a table called `UserDisplayData` under the `Tables` folder:

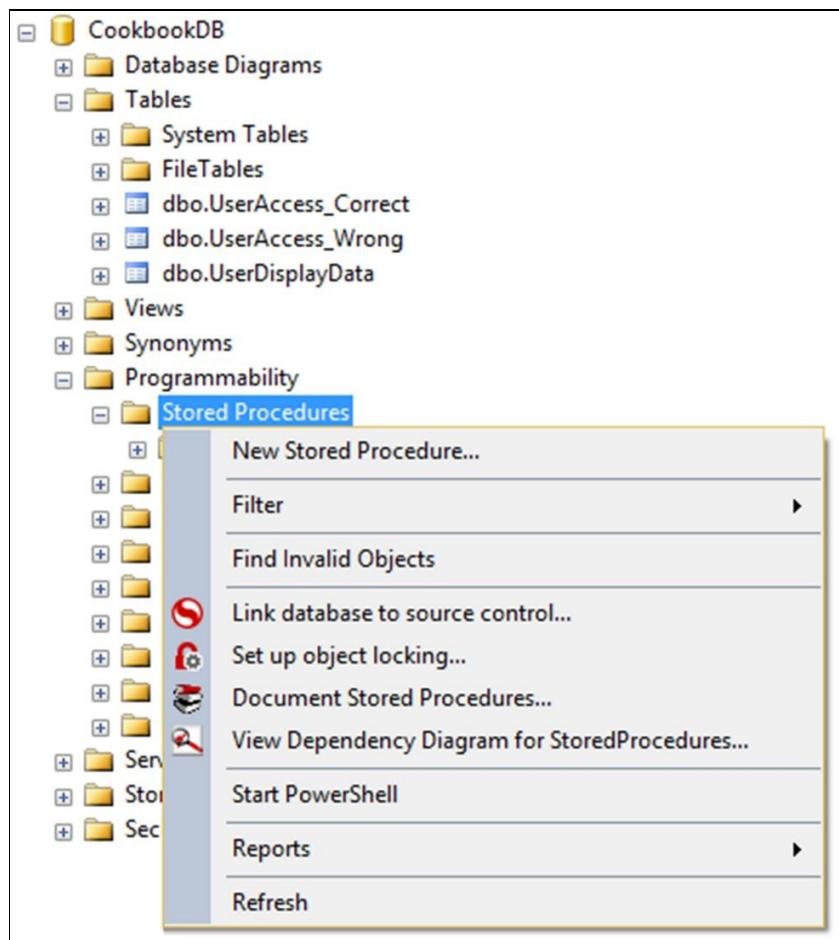

2. The `UserDisplayData` table is simply used to illustrate the concept of querying using a parameterized stored procedure. It would not have any real benefit in a production database, because it only returns a screen name:

ID	Firstname	Lastname	Displayname
1	Dirk	Strauss	Dirk Strauss
2	Jane	Smith	Jane Smith

3. We need to create a stored procedure to select data from this table for a specific ID (user ID). Click on the `Programmability` node to expand it:

4. Next, right-click on the `Stored Procedures` node and select `New Stored Procedure...` from the context menu:

5. SQL Server will create the following stored procedure template for you. This template consists of a section where you can comment on the particular stored procedure, as well as a section to add parameters you might need, and obviously a section that you need to add the actual SQL statement to:

```
SET ANSI_NULLS ON
GO
SET QUOTED_IDENTIFIER ON
GO
-- =====
-- Author:      <Author,,Name>
-- Create date: <Create Date,,>
-- Description: <Description,,>
-- =====
CREATE PROCEDURE <Procedure_Name, sysname, ProcedureName>
    -- Add the parameters for the stored procedure here
    <@Param1, sysname, @p1> <Datatype_For_Param1, , int> =
    <@Param2, sysname, @p2> <Datatype_For_Param2, , int> =
        <Default_Value_For_Param1, , 0>
        <Default_Value_For_Param2, , 0>
AS
BEGIN
    -- SET NOCOUNT ON added to prevent extra result sets      from
    -- interfering with SELECT statements.
    SET NOCOUNT ON;

    -- Insert statements for procedure here
    SELECT <@Param1, sysname, @p1>, <@Param2, sysname, @p2>
END
GO
```

6. Give the stored procedure a suitable name that will describe the action or intent of the stored procedure:

```
| CREATE PROCEDURE cb_ReadCurrentUserDisplayData
```

*There are many people that do prefix their stored procedures, and I'm one of those. I like to keep my stored procedures grouped. I, therefore, name my stored procedures in the format [prefix]\_[tablename\_or\_module]\_[stored\_procedure\_action]. Having said that, I generally avoid using sp\_ as a prefix to my stored procedures. There are a lot of opinions on the Internet as to why this is a bad idea. It is generally believed that using sp\_ as a stored procedure prefix impacts on performance because it is used as the stored procedure prefix in the master database. For the purposes of this recipe, I have just kept to a simple name for the stored procedure.*

7. Define a parameter for this stored procedure. By doing this, you are telling the database that when this stored procedure is called, it will pass through a value of type integer that is stored in a parameter caller @userID:

```
| @userID INT
```

8. You now define the SQL statement to be used by this stored procedure. We are just going to do a straightforward SELECT statement:

```
SELECT
    Firstname, Lastname, Displayname
FROM
    dbo.UserDisplayData
WHERE
    ID = @userID
```

*You will notice that my SELECT statement contains the specific column names instead of a SELECT \* FROM. Doing a SELECT \* is considered bad practice. You would usually not want to*

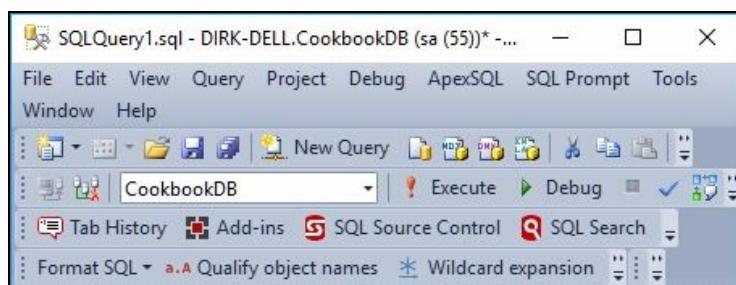

**i** return all the column values from a table. If you want all the column values, then it is better to explicitly list the columns by name instead of just getting all. Using `SELECT *` returns unnecessary columns and increases the overhead on the server. This does make a difference in the bigger scheme of things, especially when the database starts getting a lot of traffic. The thought of having to type out the column names for a large table is definitely not something I would look forward to. You can, however, use the following tricks to make it easy for you to add the column names to your SQL `SELECT` statement. You can right-click on the database table and select `Script Table As` to create one of several SQL statements. Secondly, you can expand the `Table` node and expand the table you wish to write the statement for. You will then see a node called `columns`. Drag the `columns` node onto the query editor. That will insert all the column names into the query editor for you.

- When you have completed adding the code to your stored procedure, it will look like this:

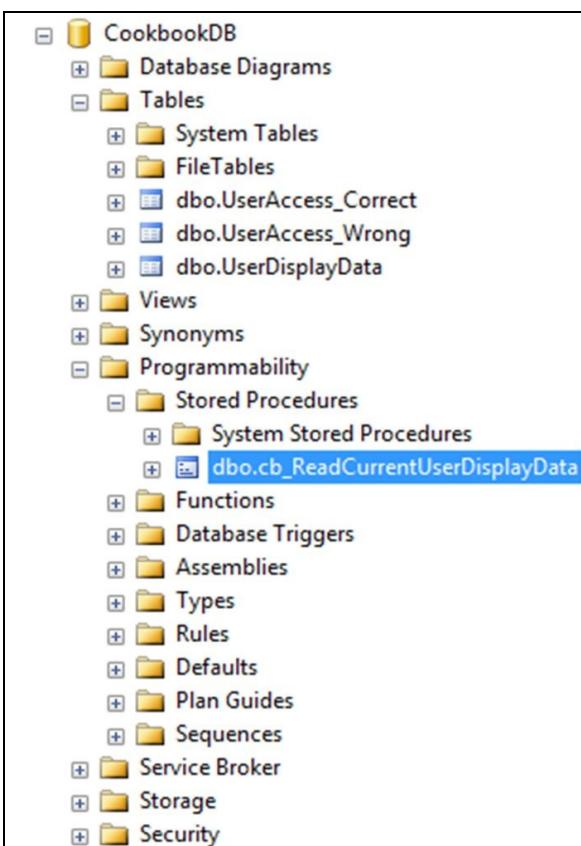

```
SET ANSI_NULLS ON
GO
SET QUOTED_IDENTIFIER ON
GO
-- =====
-- Author:      <Dirk Strauss>
-- Create date: <2 April 2016>
-- Description: <Read the user data for the specific user ID supplied as parameter>
-- =====
CREATE PROCEDURE cb_ReadCurrentUserDisplayData
    @userID INT
AS
BEGIN
    -- SET NOCOUNT ON added to prevent extra result sets from
    -- interfering with SELECT statements.
    SET NOCOUNT ON;

    SELECT
        Firstname, Lastname, DisplayName
    FROM
        dbo.UserDisplayData
    WHERE
        ID = @userID
END
GO
```

- To create the stored procedure, you need to click on the Execute button. Be certain that you have the correct database selected when clicking on the Execute button:

- The stored procedure will then be created under the `stored Procedures` node in SQL Server:

12. We have now come halfway through this task. It is time to construct the code that we will use in our application to query the database. We will be adding this code directly to the `Program.cs` file of your console application. While this code isn't considered best practice (hardcoding the server credentials), it serves merely to illustrate the concept of calling a parameterized stored procedure from C#.

13. To start, add the following `using` statement to the top of your console application:

```
| using System.Data.SqlClient;
```

14. We then add the variables to contain the credentials we need to log on to the server:

```
int intUserID = 1;
    int cmdTimeout = 15;
    string server = "DIRK";
    string db = "CookbookDB";
    string uid = "dirk";
    string password = "uR^GP2ABG19@!R";
```

15. We now use `SecureString` to store the password and add it to a `SqlCredential` object:

```
SecureString secpw = new SecureString();
    if (password.Length > 0)
    {
        foreach (var c in password.ToCharArray()) secpw.AppendChar(c);
    }
    secpw.MakeReadOnly();

    string dbConn = $"Data Source={server};Initial Catalog={db}";
    SqlCredential cred = new SqlCredential(uid, secpw);
```

*For more on `SecureString`, see the [Using `SecureString` in code](#) recipe of this chapter.*

16. We now create a `SqlConnection` object inside a `using` statement. This ensures that the SQL connection is closed when the `using` statement moves out of scope:

```
using (SqlConnection conn = new SqlConnection(dbConn, cred))
{
    try
    {

    }
    catch (Exception ex)
    {
        Console.WriteLine(ex.Message);
    }
}
Console.ReadLine();
```

17. Inside the `try`, add the following code to open the connection string and create a `SqlCommand` object that takes the open connection and name of the stored procedure as parameters. You can use the shortcut method of creating the actual SQL parameter to pass to the stored procedure:

```
| cmd.Parameters.Add("userID", SqlDbType.Int).Value = intUserID;
```

Because I'm just passing a parameter of type integer to the stored procedure, I'm not defining a length for this parameter:

```
cmd.Parameters.Add("userID", SqlDbType.Int).Value = intUserID;
▲ 3 of 4 ▼ SqlParameter SqlParameterCollection.Add(string parameterName, SqlDbType sqlDbType, int size)
    Adds a SqlParameter to the SqlParameterCollection, given the specified parameter name, SqlDbType and size.
    SqlDbType: The SqlDbType of the SqlParameter to add to the collection.
```

If, however, you ever need to define a parameter of type `varchar(MAX)`, you would need to define the size of the parameter type by adding `-1`. Let's say, for example, you need to store a student's essay in the database; the code would then look as follows for the `varchar(MAX)`:

```
cmd.Parameters.Add("essay", SqlDbType.VarChar, -1).Value =
essayValue;
```

18. After we have added our parameter with its value to the `SqlCommand` object, we specify a timeout value, execute the `SqlDataReader`, and load it into a `DataTable`. The value is then output to the console application:

```
conn.Open();
SqlCommand cmd = new SqlCommand("cb_ReadCurrentUserDisplayData",
    conn);
cmd.CommandType = CommandType.StoredProcedure;
cmd.Parameters.Add("userID", SqlDbType.Int).Value = intUserID;
cmd.CommandTimeout = cmdTimeout;
var returnData = cmd.ExecuteReader();
var dtData = new DataTable();
dtData.Load(returnData);

if (dtData.Rows.Count != 0)
    Console.WriteLine(dtData.Rows[0]["Displayname"]);
```

19. After you have added all the code to your console application, the correct completed code will look as follows:

```
int intUserID = 1;
int cmdTimeout = 15;
string server = "DIRK";
string db = "CookbookDB";
```

```

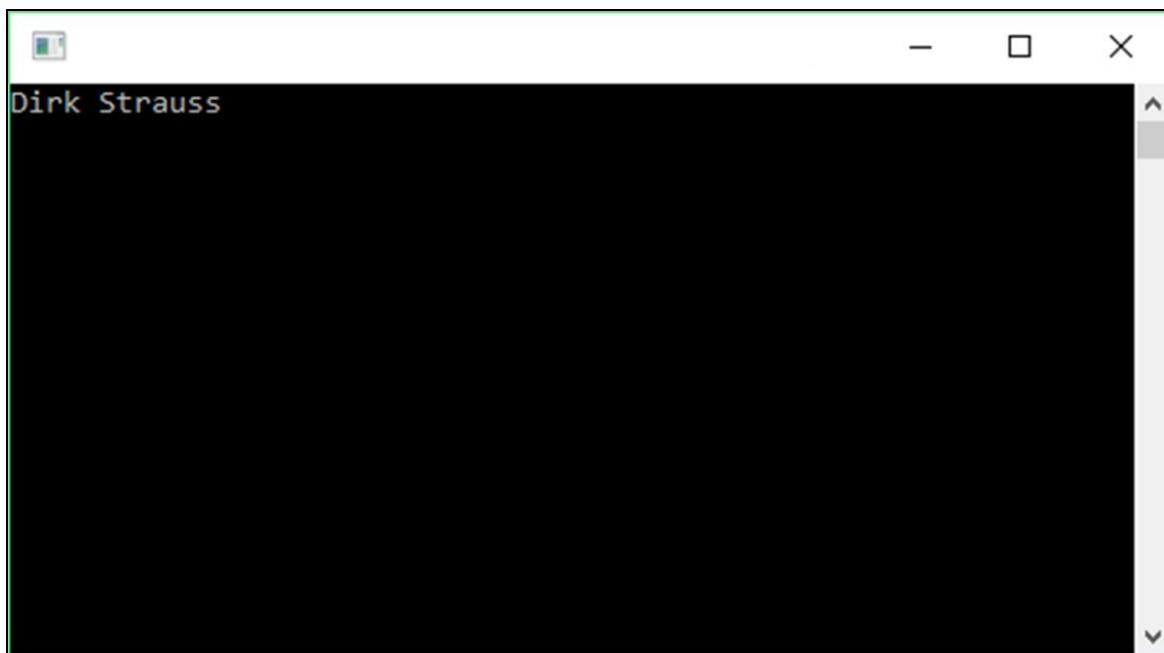

string uid = "dirk";
string password = "uR^GP2ABG19@!R";
SecureString secpw = new SecureString();
if (password.Length > 0)
{
    foreach (var c in password.ToCharArray())
        secpw.AppendChar(c);
}
secpw.MakeReadOnly();

string dbConn = $"Data Source={server};Initial Catalog={db}"; 

SqlCredential cred = new SqlCredential(uid, secpw);
using (SqlConnection conn = new SqlConnection(dbConn, cred))
{
    try
    {
        conn.Open();
        SqlCommand cmd = new SqlCommand(
            "cb_ReadCurrentUserDisplayData", conn);
        cmd.CommandType = CommandType.StoredProcedure;
        cmd.Parameters.Add("userID", SqlDbType.Int).Value = intUserID;
        cmd.CommandTimeout = cmdTimeout;
        var returnData = cmd.ExecuteReader();
        var dtData = new DataTable();
        dtData.Load(returnData);
        if (dtData.Rows.Count != 0)
            Console.WriteLine(dtData.Rows[0]["Displayname"]);
    }
    catch (Exception ex)
    {
        Console.WriteLine(ex.Message);
    }
}
Console.ReadLine();

```

20. Run your console application and you will see the display name output to the screen:

# How it works...

By creating a parameterized SQL query, the compiler correctly substitutes the arguments before running the SQL statement against the database. It will prevent malicious data changing your SQL statement in order to exact a malicious result. This is because the `sqlcommand` object does not directly insert the parameter values into the statement.

To sum it all up, using parameterized stored procedures means no more Little Bobby Tables.

# Using IntelliTrace, diagnostic tools, and historical debugging

The trusty old bug has been the bane of software developers and engineers for more than 140 years. Yes, you read that right. It was in fact Thomas Edison that coined the term "bug" in the late 1870s. It appeared in many of his notebook entries where he describes for example that the incandescent lightbulb still had many "bugs left".

His efforts to debug his inventions are quite legendary. Consider the true grit and determination it took for a man already in his mid-sixties to work 112-hour working weeks. He and his seven-person team (it is a common misconception that there were only six because the seventh member didn't appear in the group photograph) became known as the insomnia squad during a 5-week stint that resulted in very little sleep.

These days, thanks to the advances of technology, software developers have a vast array of debugging tools (inside and outside of Visual Studio) at their disposal. So does debugging really matter? Of course it does. It is part of what we as software developers do. If we don't debug, well, here are some examples:

- In 2004, the **Electronic Data Systems (EDS)** child support system in the UK overpaid almost 2 million people, while underpaying almost a million, and resulted in billions of dollars in uncollected child support payments. The incompatibility between EDS and another system it relied on resulted in taxpayers losing money and negatively affecting the lives of so many single parents.
- The initial release of Apple Maps in 2012. Enough said. While bemusing for many, I still find myself using Google Maps for turn-by-turn directions when in an unfamiliar city or area.
- The Therac-25 radiation therapy machine used electrons to target tumors in patients. Unfortunately, a race condition in the software caused the machine to deliver lethal overdoses of radiation in several patients.

Examples of software bugs affecting the lives of millions of people can be found all over the Internet. We're not simply talking about the run-of-the-mill bugs either. Sometimes, we're faced with seemingly insurmountable issues. It is the comfort of knowing how to use some of the tools available that makes the difference between a stable application and one that is totally unusable.

# Getting ready

Note that IntelliTrace is only available in the Enterprise edition of Visual Studio. See the <https://www.visualstudio.com/vs/compare/> link for comparisons between the versions of Visual Studio. IntelliTrace is not a new feature in Visual Studio. It has evolved over time (since Visual Studio 2010) into what we have available today.

```
using System.Diagnostics; <br/> using System.Reflection; <br/> using System.IO;

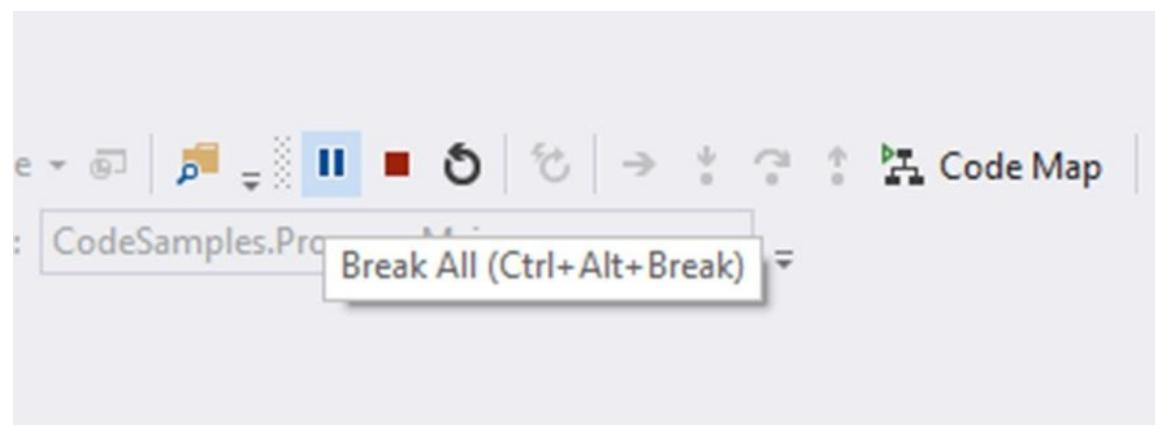

public static void ErrorInception() <br/> { <br/> string basepath =
Path.GetDirectoryName(<br/> Assembly.GetEntryAssembly().Location); <br/> var full =
Path.Combine(basepath, "log"); <br/> } <br/><br/> private static void
LogException(string message) <br/> { <br/><br/> }

try <br/> { <br/> for (int i = 0; i <= 3; i++) <br/> { <br/> // do work <br/> File.Open($""
{full}log.txt", FileMode.Append); <br/> } <br/> } <br/> catch (Exception ex) <br/> {
<br/> StackTrace st = new StackTrace(); <br/> StackFrame sf = st.GetFrame(0); <br/>
MethodBase currentMethodName = sf.GetMethod(); <br/> ex.Data.Add("Date",
DateTime.Now); <br/> LogException(ex.Message); <br/> }

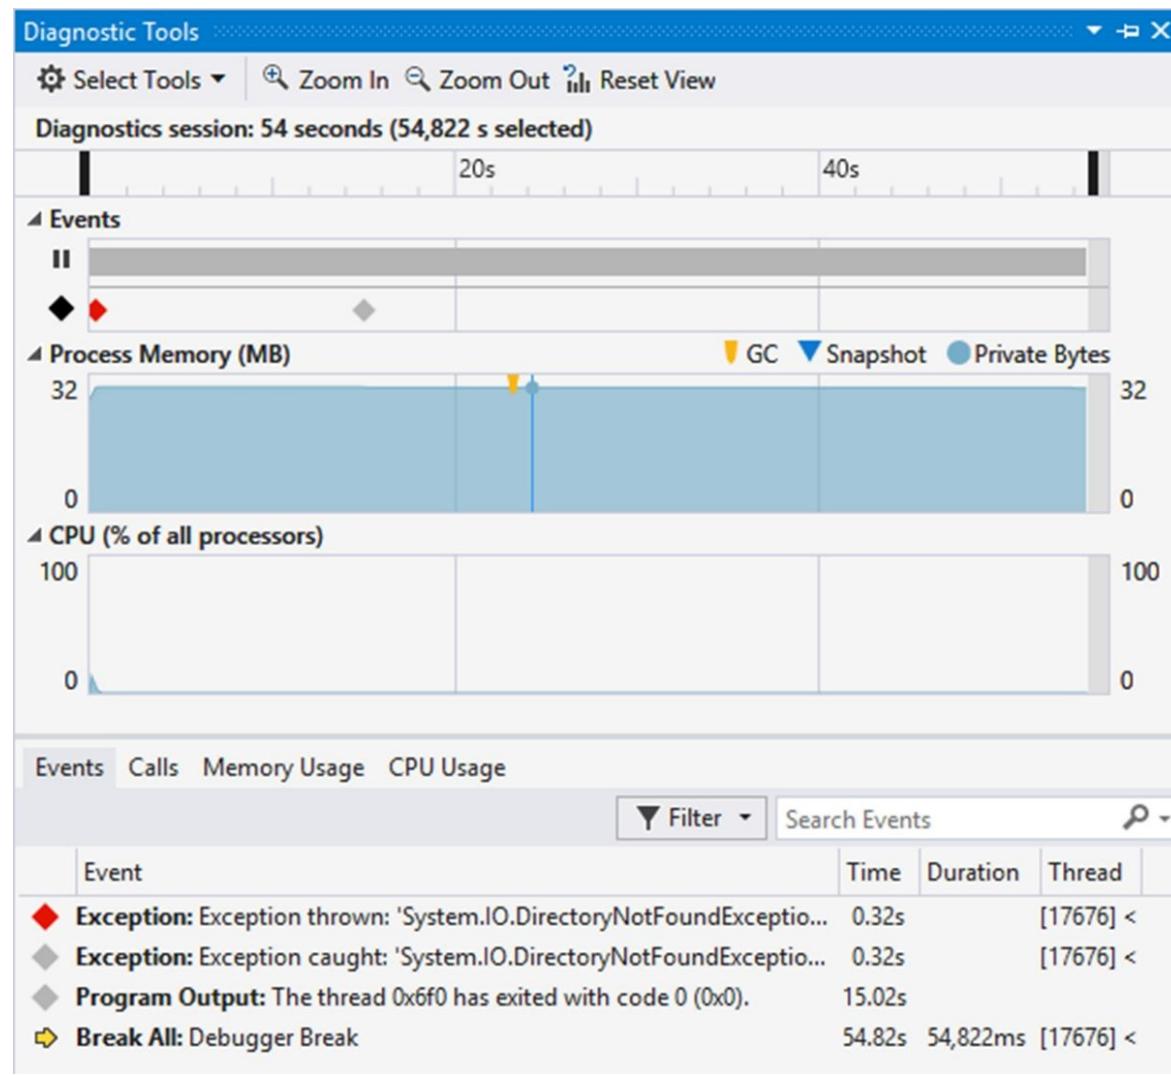

public static void ErrorInception() <br/> { <br/> string basepath =
Path.GetDirectoryName(<br/> Assembly.GetEntryAssembly().Location); <br/> var full =
Path.Combine(basepath, "log"); <br/><br/> try <br/> { <br/> for (int i = 0; i <= 3; i++)
<br/> { <br/> // do work <br/> File.Open($"'{full}'log.txt", FileMode.Append); <br/> }
<br/> } <br/> catch (Exception ex) <br/> { <br/> StackTrace st = new StackTrace(); <br/>
StackFrame sf = st.GetFrame(0); <br/> MethodBase currentMethodName =
sf.GetMethod(); <br/> ex.Data.Add("Date", DateTime.Now); <br/>
LogException(ex.Message); <br/> } <br/> } <br/><br/> private static void
LogException(string message) <br/> { <br/><br/> }

ErrorInception(); <br/> Console.ReadLine();
```

8. Start debugging your application. The exception is thrown and the application continues running, a condition often experienced with much more complex applications. At this point, you would expect a log file to be appended with the fictitious data of the app, but nothing happened. It is, at this point, that you stop your application and start adding breakpoints all over your code in a hit and miss-type exercise. I say hit and miss because you probably won't know exactly where the error is. This is especially true if your code file contains a few thousand lines of code. Well now with IntelliTrace and historical debugging, you just need to click on the Break All button:

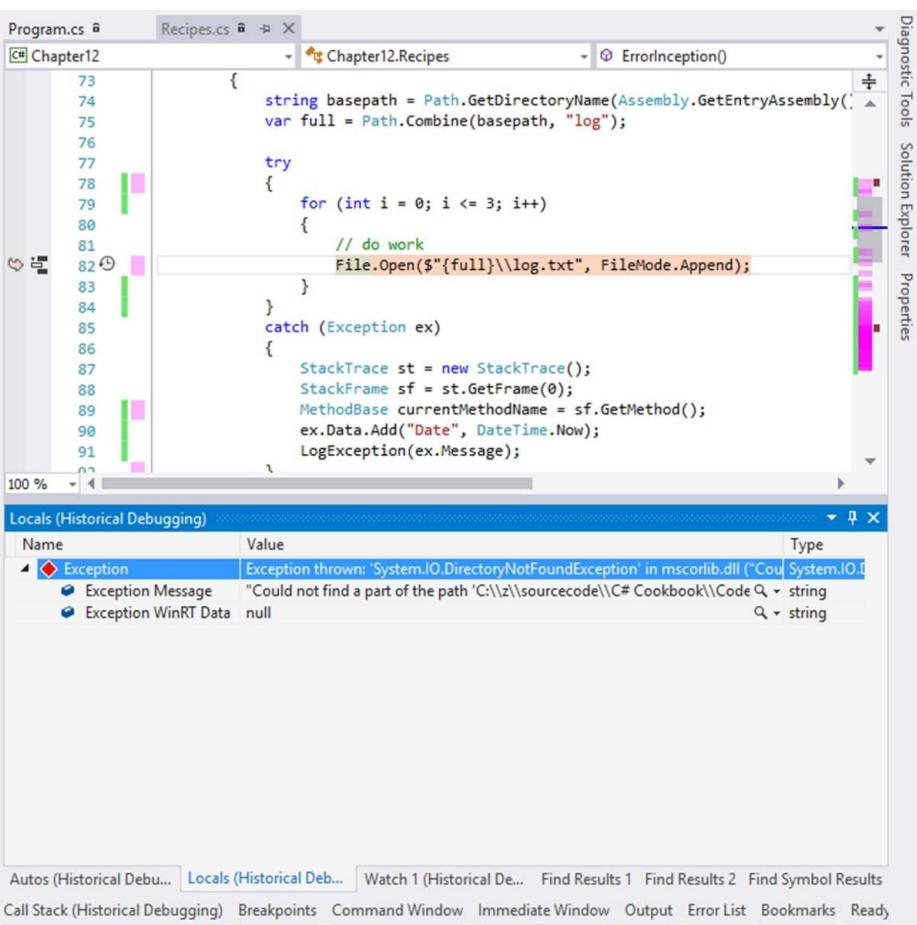

9. Your application is now essentially paused. If you don't see the Diagnostic Tools window, hold down *Ctrl + Alt + F2*.
10. Visual Studio now displays the Diagnostic Tools window. Immediately, you can see that there is a problem indicated by the red diamond icon on the Events section. In the Events tab at the bottom, you can click on the exception:

11. Doing this expands the exception details where you can see that the log file was not found. Visual Studio, however, goes one step further with historical debugging:

 <b>Exception:</b> Exception thrown: 'System.IO.DirectoryNotFoundException' in mscorlib.dll ("Could not find a part of the path 'C:\z\sourcecode\C# Cookbook\CodeSamples\bin\Debug\log\log.txt'.")	0.32s	[17676] <
 <b>Activate Historical Debugging</b>		
 <b>Exception:</b> Exception caught: 'System.IO.DirectoryNotFoundException' in mscorlib.dll ("Could not find a part of the path 'C:\z\sourcecode\C# Cookbook\CodeSamples\bin\Debug\log\log.txt'.")	0.32s	[17676] <
 <b>Program Output:</b> The thread 0x6f0 has exited with code 0 (0x0).	15.02s	
 <b>Break All:</b> Debugger Break	54.82s	54,822ms [17676] <

12. You will see a link at the bottom of the exception details that says Activate Historical Debugging. Click on this link. This allows you to see the actual line of code that caused this exception in the code editor. It also allows you to view the history of the applications state in the Locals window, call stack, and other windows. You can now see the specific line of code that caused the exception in your code editor. In the Locals window, you can also see what the path was that the application used to look for the log file. This kind of debugging experience is immensely powerful and allows developers to go straight to the source of the error. This leads to increased productivity and better code:

# How it works...

So what is the takeaway here? If you only remember one thing, remember this. Once the users of your system lose faith in the abilities and potential of that system due to bugs, that confidence is almost impossible to regain. Even if you resurrect your system from the ashes, after it was laid low by bugs and other issues, to produce a flawless product, your users will not be easily swayed. This is because in their mind, the system is buggy.

I once had to take over a system partially developed by a senior developer who was leaving the company. She had an excellent specification and a well presented prototype shown to the customer. The only problem was that she left the company shortly after the system's phase one was implemented. When the bugs came popping up, the client naturally asked for her assistance.

Telling the client that the developer (who had been solely responsible for building a relationship with the client) had left the company did not bode well to instill a sense of confidence. Having a single developer involved was the first mistake of this particular project anyway.

Secondly, phase two was about to be developed by yours truly, who was also the only developer assigned to this client. This had to be done while building on top of the buggy phase one. So, I was fixing bugs while developing new features for the system. Luckily this time round, I had a fantastic project manager called Rory Shelton as my wingman. Together, we were dumped in the deep end and Rory did a fantastic job managing the client's expectations while being totally transparent with the client regarding the challenges we were facing.

The users were unfortunately already disillusioned with the provided system and didn't trust the software. This trust was never fully regained. If we had IntelliTrace and historical debugging back in 2007, I definitely would have been able to track down the issues in a code base that was unfamiliar to me.

Always debug your software. When you find no more bugs, debug it again. Then give the system to my mom (love you mom). You, as the developer of that system, know which buttons to click on and what data to enter, and in which order things need to happen. My mom doesn't and I can assure you that a user unfamiliar with a system can break it quicker than you can brew a fresh cup of coffee.

Visual Studio provides developers with a very powerful and feature rich set of debugging tools. Use them.

# **Setting conditional breakpoints**

Conditional breakpoints are another hidden gem when it comes to debugging. This allows you to specify one or several conditions. When one of these conditions is met, the code will stop at the breakpoint. Using conditional breakpoints is really easy.

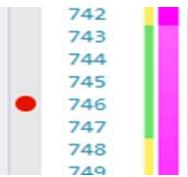

# Getting ready

There is nothing you specifically need to prepare to use this recipe.

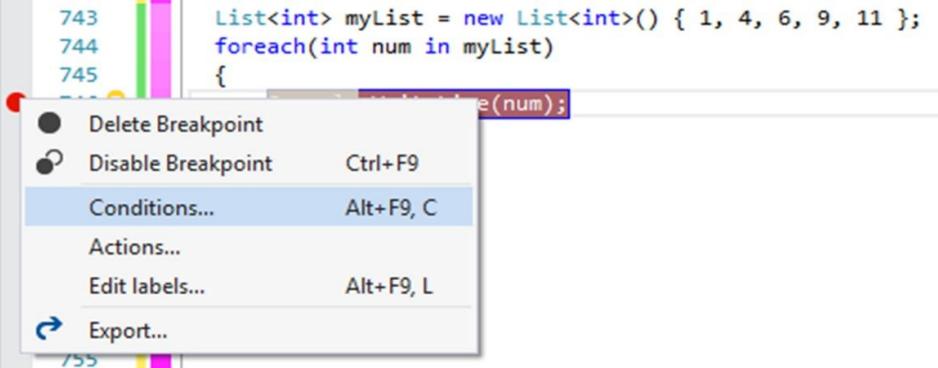

```
List<int> myList = new List<int>() { 1, 4, 6, 9, 11 };<br/> foreach(int num in myList)<br/> { <br/> Console.WriteLine(num); <br/> } <br/> Console.ReadLine();
```

2. Next, place a breakpoint on the `Console.WriteLine(num)` line of code inside the loop:

```
742  
743  
744  
745  
746 List<int> myList = new List<int>() { 1, 4, 6, 9, 11 };  
747 foreach(int num in myList)  
748 {  
749     Console.WriteLine(num);  
750 }  
751 Console.ReadLine();
```

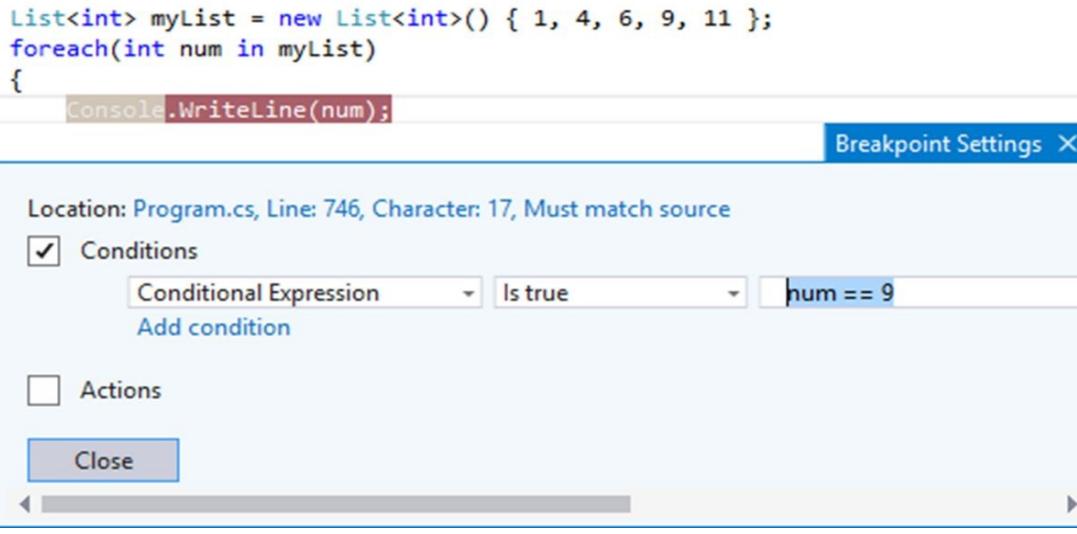

3. Right-click on the breakpoint and select Conditions... from the context menu:

```
743 List<int> myList = new List<int>() { 1, 4, 6, 9, 11 };  
744 foreach(int num in myList)  
745 {  
    Console.WriteLine(num);  
}
```

- Delete Breakpoint
- Disable Breakpoint Ctrl+F9
- Conditions...** Alt+F9, C
- Actions...
- Edit labels... Alt+F9, L
- Export...

4. You will now see that Visual Studio opens a Breakpoint Settings window. Here we specify that the breakpoint needs to be hit only when the value of `num` is 9. You can add several conditions and specify different conditions. The condition logic is really flexible:

5. Debug your console application. You will see that when the breakpoint is hit, the value of `num` is 9:

```
743  
744  
745  
746 List<int> myList = new List<int>() { 1, 4, 6, 9, 11 };  
747 foreach(int num in myList)  
{  
    Console.WriteLine(num);  
}  
Console.ReadLine();  
748  
749
```

100 %

Autos

Name	Value
myList	Count = 5
num	9

# How it works...

The condition is evaluated on every loop. When the condition is true, the breakpoint will be hit. In the example illustrated in this recipe, the true benefit of a conditional breakpoint is somewhat lost because it is a very small list. Consider this though. You are binding a data grid. Items on the grid are given specific icons based on the status of the item. Your grid contains hundreds of items, because this is a hierarchical grid. You identify the primary ID of the item which is bound to the grid. This primary ID is then passed to other code logic to determine the status, which determines the icon displayed.

To debug and pressing *F10* through hundreds of loops is not productive in any event. With conditional breakpoints, you can specify a value for the primary ID, and only break when the loop hits that value. You can then go straight to the item that is being displayed incorrectly.

# Using PerfTips to identify bottlenecks in code

PerfTips are definitely one of my favorite features of Visual Studio. Explaining what they do doesn't do them justice. You have to see them in action.

# Getting ready

Do not confuse PerfTips with CodeLens. It is a separate option from CodeLens in Visual Studio.

```
public static void RunFastTask() <br/> { <br/> RunLongerTask(); <br/> } <br/><br/>private static void RunLongerTask() <br/> { <br/> Thread.Sleep(3000); <br/> BottleNeck(); <br/> } <br/><br/> private static void BottleNeck() <br/> { <br/> Thread.Sleep(8000); <br/> }
```

RunFastTask(); <br/> Thread.Sleep(1000);

4. Start debugging your console application. Your breakpoint will stop on the RunFastTask() method. Hit *F10* to step over this method:

```
RunFastTask();  
Thread.Sleep(1000);  
}
```

5. You will notice that 11 seconds later, the next line will be highlighted and the PerfTip will be displayed. The PerfTip displays the time it took for the previous line of code to execute. So, the debugger that now sits on the Thread.Sleep, shows that the RunFastTask() method took 11 seconds to complete. The task is clearly not very fast:

```
RunFastTask();  
Thread.Sleep(1000); ≤11 022ms elapsed  
}
```

6. Stepping into the RunFastTask() method, you can place further breakpoints and step over them one by one to find the method that is causing the longest delay. As you can see, PerfTips allow developers to quickly and easily identify bottlenecks in code:

```
1 reference
public static void RunFastTask()
{
    RunLongerTask();
}

1 reference
private static void RunLongerTask()
{
    Thread.Sleep(3000);
    BottleNeck();
}

1 reference
private static void BottleNeck()
{
    Thread.Sleep(8000);
}
```

≤ 8 001ms elapsed

# **How it works...**

There are many tools on the market that do this and much more, allowing developers to view all sorts of code metrics. PerfTips, however, allow you to see issues on the fly while you are stepping through your code as per your normal debugging tasks. It is, in my opinion, an indispensable debugging tool.

# Creating Microservices on Azure Service Fabric

This chapter deals with the exciting world of microservices and **Azure Service Fabric**. In this chapter, we will cover the following recipes:

- Downloading and installing Service Fabric
- Creating a Service Fabric application with a stateless actor service
- Using Service Fabric Explorer

# Introduction

Traditionally, developers wrote applications in a monolithic manner. This means one single executable that is broken up into components via classes and so on. Monolithic applications require a great deal of testing, and deployment is tedious due to the bulkiness of the monolithic application. Even though you might have multiple developer teams, they all need to have a solid understanding of the application as a whole.

Microservices is a technology that aims to address the issues surrounding monolithic applications and the traditional way of developing applications. With microservices, you can break the application into smaller bits (services) that can function on their own without being dependent on any of the other services. These smaller services can be stateless or stateful and are also smaller in scale of functionality, making them easier to develop, test, and deploy. You can also version each microservice independently from the others. If one microservice is receiving more load than the others, you can scale only that service up to meet the demands placed on it. With monolithic applications, you would have to try and scale the whole application up in order to meet the demands for a single component within the application.

Take, for example, the workings of a popular online web store. It could consist of a shopping cart, shopper profile, order management, backend login, inventory management, billing, returns, and much more. Traditionally, a single web application is created to provide all these services. With microservices, you can isolate each service as a standalone, self-contained bit of functionality and code base. You can also dedicate a team of developers to work on a single portion of the web store. If this team is responsible for the inventory-management microservice, they would handle every aspect of it. This, for example, means everything from writing code and enhancing functionality to testing and deployment.

Another excellent side effect of microservices is that it allows you to easily isolate any faults you might come across. Finally, you can also create microservices in any technology you want (C#, Java, and VB.NET), as they are language-independent.

Azure Service Fabric allows you to scale your microservices easily and increases application availability because it implements failover. When microservices are used with the Service Fabric, microservices become a very powerful technology. Think of Azure Service Fabric as a **Platform as a Service (PaaS)** solution on top of which your microservices sit. We call the collection that the microservices live on a Service Fabric cluster. Each microservice lives on a virtual machine, which is referred to as a node in the Service Fabric cluster. This Service Fabric cluster can live in the cloud or on a local machine. If a node becomes unavailable due to any reason, the Service Fabric cluster will automatically redistribute the microservices to the other nodes so that the application remains available.

Finally, here is a word on the differences between stateful and stateless microservices. You are able to create a microservice as stateless or stateful. When a microservice relies on an external data store to persist data, it is stateless in nature. This simply means that the microservice does not maintain its state internally. A stateful microservice, on the other hand, maintains its own state by storing it locally on the server it resides on. As you can imagine, stateful microservices are nicely suited for financial transactions. If a node had to go down for whatever reason, the state of that transaction will be persisted when the failover happens and continue where it left off on the new node.

# Downloading and installing Service Fabric

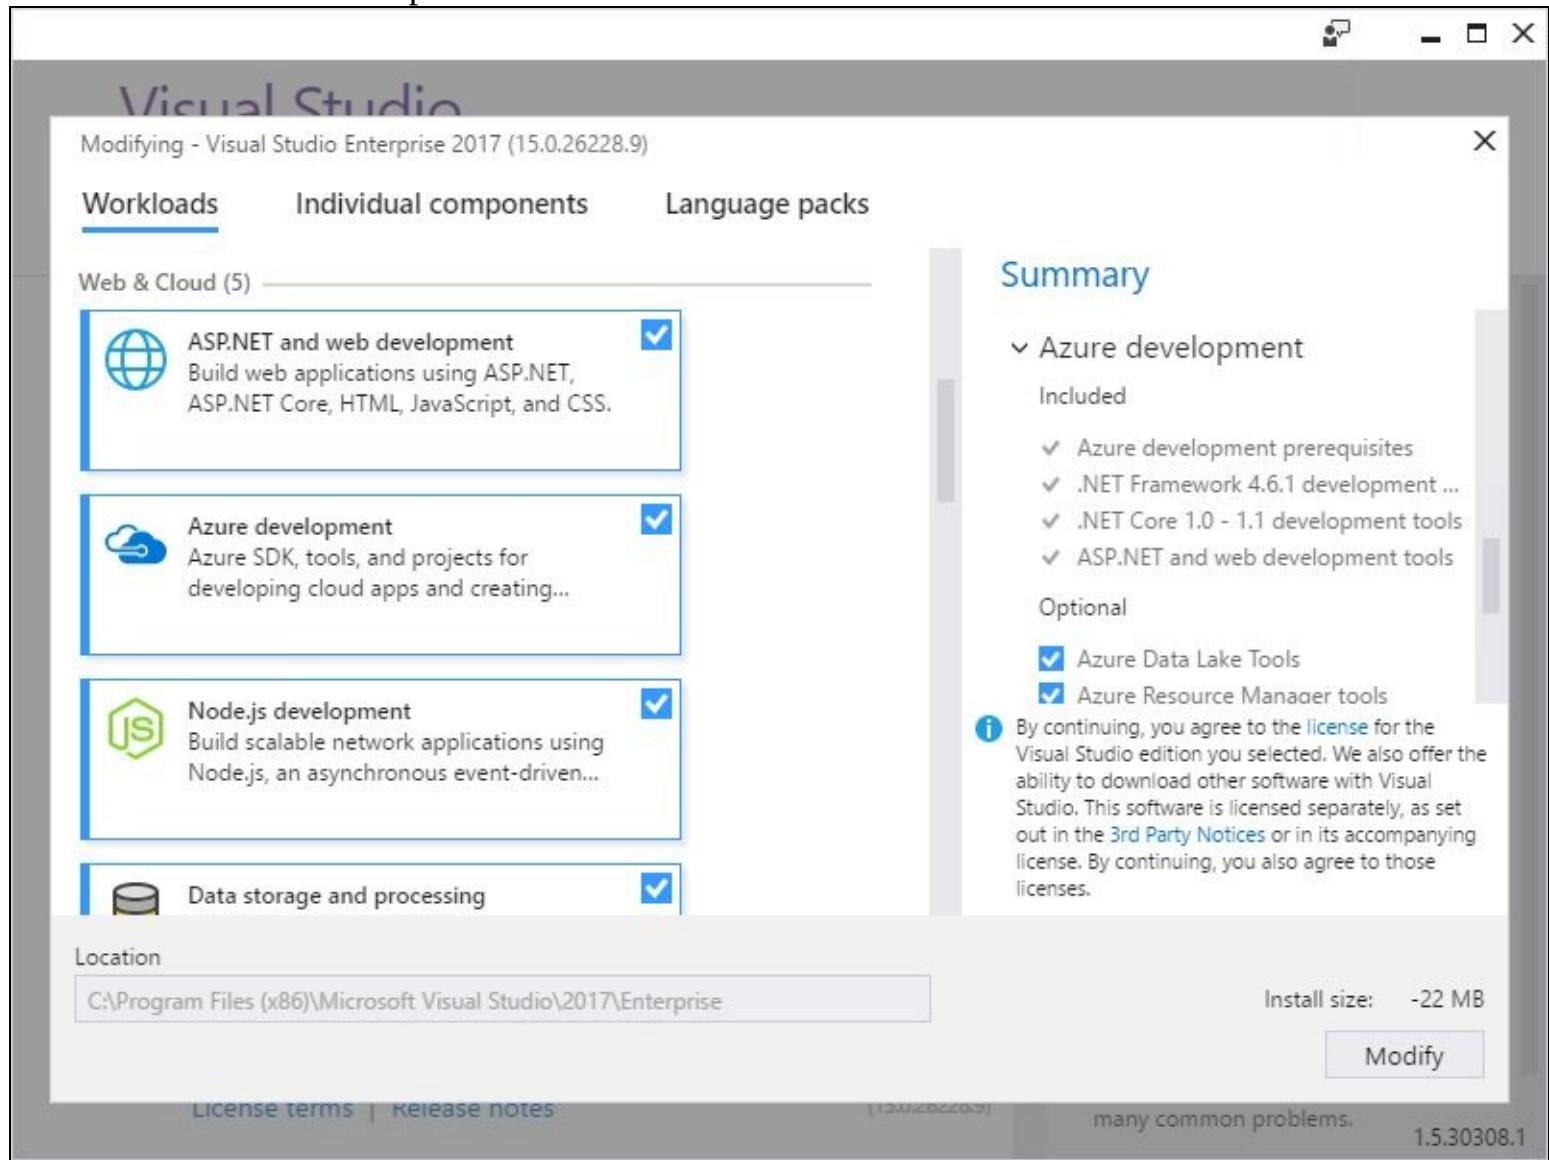

You will have to install and set up a local Service Fabric cluster on your PC before you can create and test Service Fabric applications. The local Service Fabric cluster is a fully functional cluster, as it would be in a live environment.

# Getting ready

We will download and install the **Microsoft Azure Service Fabric SDK** from the Azure site. This will allow you to create a local Service Fabric cluster on your local development machine. For more information, have a look at <https://docs.microsoft.com/en-us/azure/service-fabric/service-fabric-get-started>.

The Service Fabric tools are now part of the Azure development and management workload in Visual Studio 2017. Enable this workload when you install Visual Studio 2017. You will also need to enable the ASP.NET and web development workload:

**TIP** Note that if you do not have the original installer for Visual Studio anymore, and didn't enable the Azure Development and Management workload during installation, you can still enable this. Download the web platform installer for the version of Visual Studio 2017 you have and click on it. This will launch the installer, but will allow you to modify your existing Visual Studio 2017 installation. You can also run the installer from the New Project dialog screen in Visual Studio 2017. If you collapse the installed templates, you will see a section that allows you to open the Visual Studio Installer.

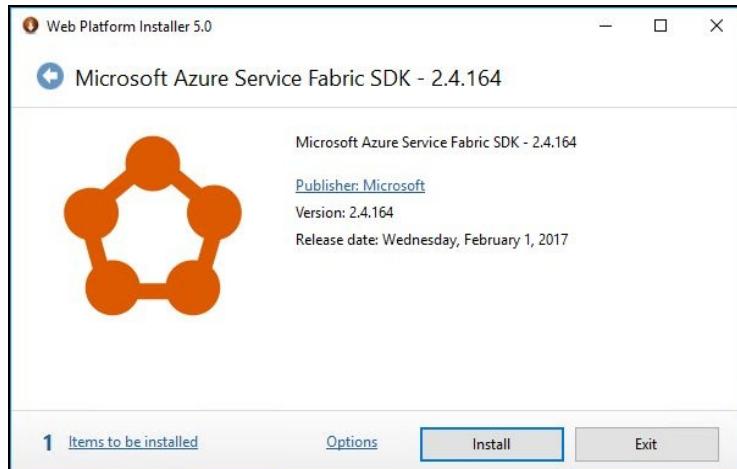

In addition to that, you can install the Microsoft Azure Service Fabric SDK using the Web Platform

Installer from the preceding link. It will read Install the Microsoft Azure Service Fabric SDK. For the best installation experience, it is advisable to launch the Web Platform Installer using Internet Explorer or Edge browsers.

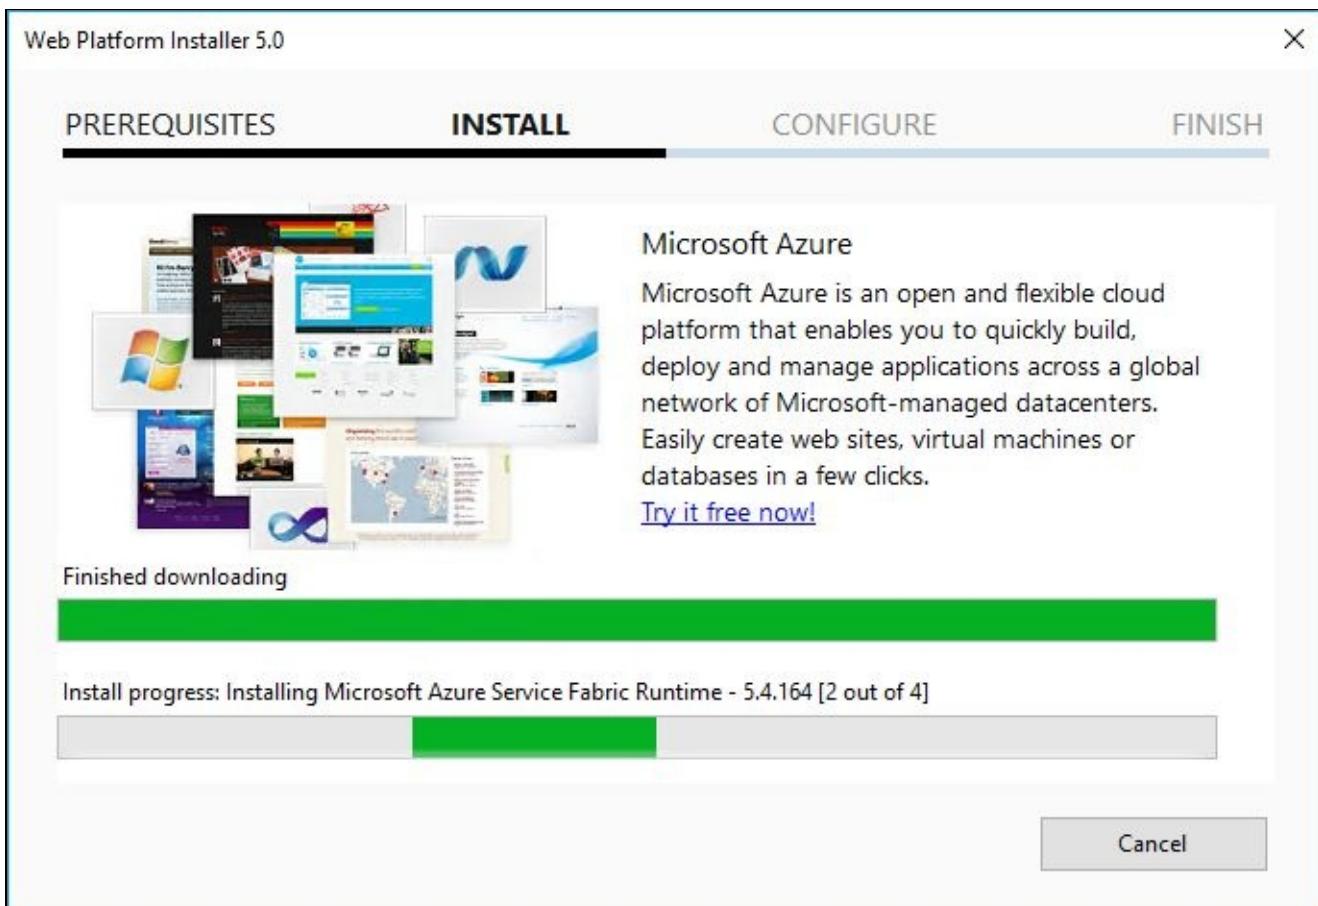

# How to do it...

1. From the Microsoft Azure site, download the Microsoft Azure Service Fabric SDK and access other resources, such as documentation via the Service Fabric learning path, from <https://azure.microsoft.com/en-us/documentation/learning-paths/service-fabric/>. When you click on the WPI launcher, you should see the following screen:

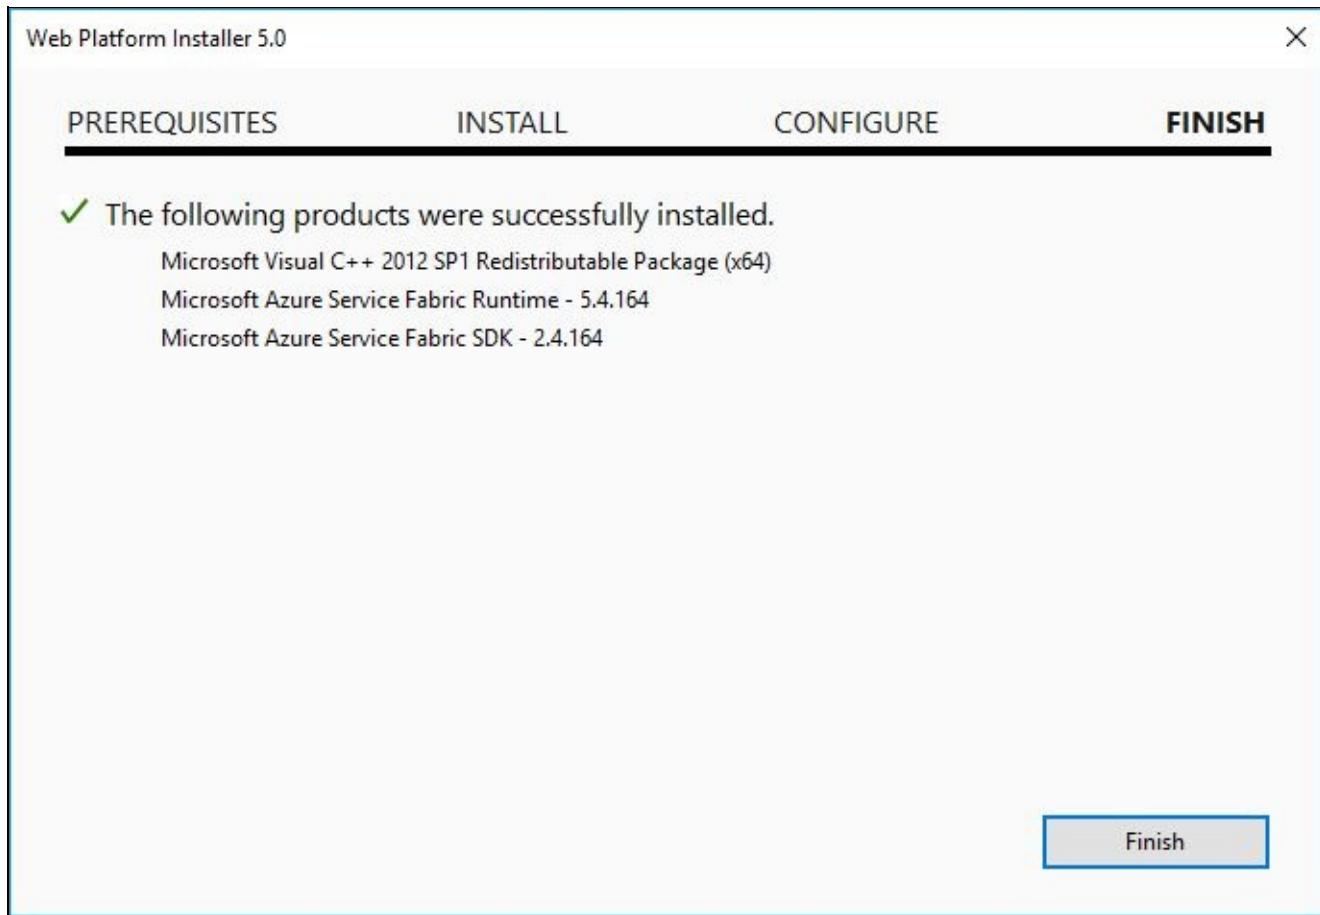

2. You will need to accept the license terms before the installation begins.
3. The web platform installer then starts downloading Microsoft Azure Service Fabric Runtime. Allow this process to complete.
4. After the download has completed, the installation process will begin:

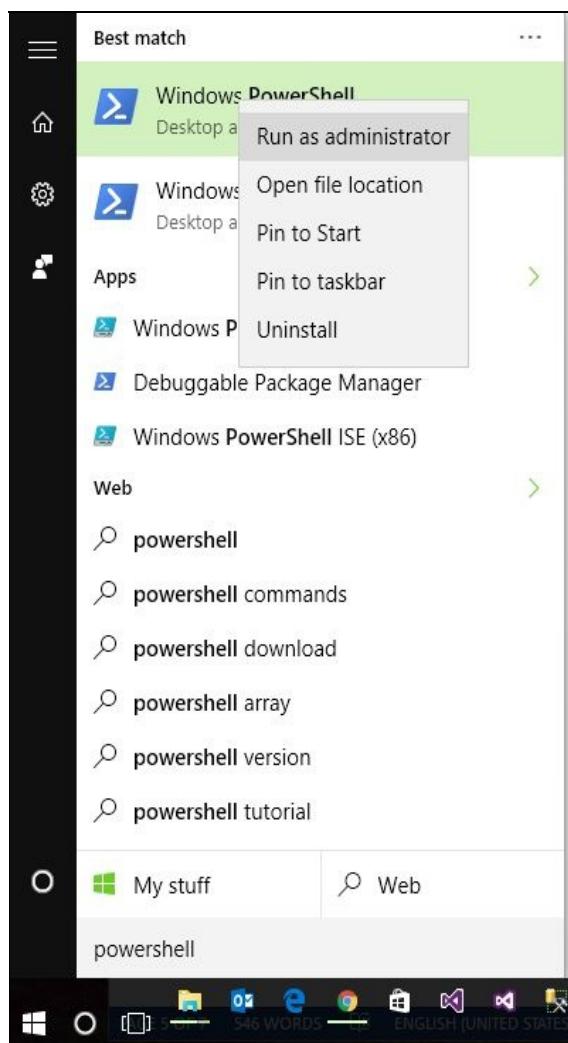

5. When the installation has completed, the following products will have been installed, which is also evident in the following screenshot:

- Microsoft Visual C++ 2012 SP1 Redistributable Package
- Microsoft Azure Service Fabric Runtime
- Microsoft Azure Service Fabric SDK

*Your installation might differ from the screenshot, depending on your specific pre-installed components.*

6. The next task is to open PowerShell as the administrator. In the Windows 10 Start menu, type the word `Powershell`, and the search will immediately return the desktop application as a result. Right-click on the desktop application and select Run as administrator from the context menu:

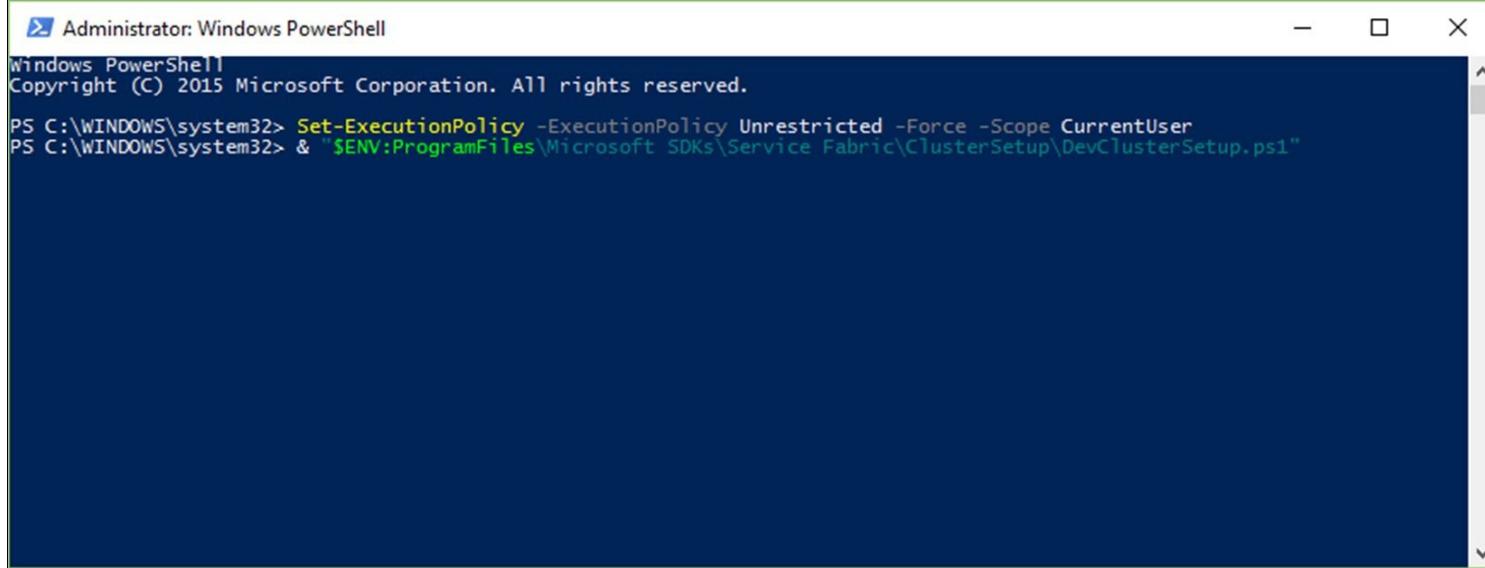

- Once Windows PowerShell has opened up, run the `Set-ExecutionPolicy -ExecutionPolicy Unrestricted -Force -Scope CurrentUser` command. The reason for this is that Service Fabric uses PowerShell scripts for the creation of the local development cluster. It is also used for the deployment of Visual Studio developed apps. Running this command prevents Windows from blocking those scripts:

```
Administrator: Windows PowerShell
Windows PowerShell
Copyright (C) 2015 Microsoft Corporation. All rights reserved.

PS C:\WINDOWS\system32> Set-ExecutionPolicy -ExecutionPolicy Unrestricted -Force -Scope CurrentUser
```

- Next, create the local Service Fabric cluster. Enter the `& "$ENV:ProgramFiles\Microsoft SDKs\Service Fabric\ClusterSetup\DevClusterSetup.ps1"` command.

This will create the local cluster needed to host Service Fabric applications:

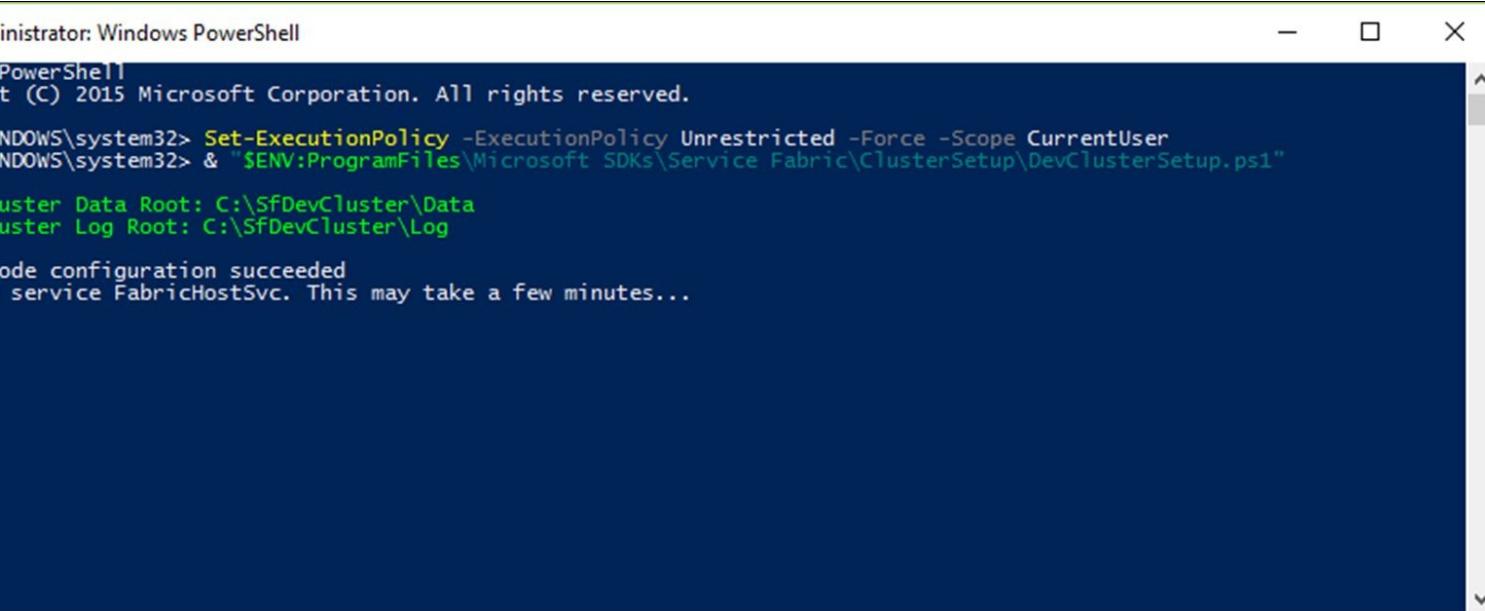

```
Administrator: Windows PowerShell
Windows PowerShell
Copyright (C) 2015 Microsoft Corporation. All rights reserved.

PS C:\WINDOWS\system32> Set-ExecutionPolicy -ExecutionPolicy Unrestricted -Force -Scope CurrentUser
PS C:\WINDOWS\system32> & "$ENV:ProgramFiles\Microsoft SDKs\Service Fabric\ClusterSetup\DevClusterSetup.ps1"
```

B06434\_17\_07

9. After the cluster is created, PowerShell will start the service:

```
Administrator: Windows PowerShell
Windows PowerShell
Copyright (C) 2015 Microsoft Corporation. All rights reserved.

PS C:\WINDOWS\system32> Set-ExecutionPolicy -ExecutionPolicy Unrestricted -Force -Scope CurrentUser
PS C:\WINDOWS\system32> & "$ENV:ProgramFiles\Microsoft SDKs\Service Fabric\ClusterSetup\DevClusterSetup.ps1"

Using Cluster Data Root: C:\SfDevCluster\Data
Using Cluster Log Root: C:\SfDevCluster\Log

Create node configuration succeeded
Starting service FabricHostSvc. This may take a few minutes...
```

10. The process might take several minutes. Be sure to let it complete:

```
Windows PowerShell
Copyright (C) 2015 Microsoft Corporation. All rights reserved.

PS C:\WINDOWS\system32> Set-ExecutionPolicy -ExecutionPolicy Unrestricted -Force -Scope CurrentUser
PS C:\WINDOWS\system32> & "$ENV:ProgramFiles\Microsoft SDKs\Service Fabric\ClusterSetup\DevClusterSetup.ps1"

Using Cluster Data Root: C:\SfDevCluster\Data
Using Cluster Log Root: C:\SfDevCluster\Log

Create node configuration succeeded
Starting service FabricHostSvc. This may take a few minutes...

Waiting for Service Fabric Cluster to be ready. This may take a few minutes...
Local Cluster ready status: 4% completed.
Local Cluster ready status: 8% completed.
Local Cluster ready status: 12% completed.
Local Cluster ready status: 17% completed.
Local Cluster ready status: 21% completed.
Local Cluster ready status: 25% completed.
Local Cluster ready status: 100% completed.

Waiting for Naming Service to be ready. This may take a few minutes...
```

## 11. Once the naming service is ready, you can close PowerShell:

```
Administrator: Windows PowerShell
-
X
^

Naming Service ready status: 8% completed.
Naming Service ready status: 17% completed.
Naming Service ready status: 25% completed.
Naming Service ready status: 33% completed.
Naming Service ready status: 42% completed.
Naming Service ready status: 50% completed.
Naming Service ready status: 58% completed.
Naming Service ready status: 67% completed.
Naming Service ready status: 75% completed.
Naming Service ready status: 83% completed.
Naming Service ready status: 92% completed.
Naming Service ready status: 100% completed.
WARNING: Naming Service is taking longer than expected to be ready...

Local Service Fabric Cluster created successfully.

=====
## To connect using Powershell, open an a new powershell window and connect using 'Connect-ServiceFabricCluster' command (without any arguments)."
## To connect using Service Fabric Explorer, run ServiceFabricExplorer and connect using 'Local/OneBox Cluster'."
## To manage using Service Fabric Local Cluster Manager (system tray app), run ServiceFabricLocalClusterManager.exe"
=====

PS C:\WINDOWS\system32>
```

## 12. To view the created cluster, you can navigate to <http://localhost:19080/Explorer> on your local machine.

This will give you a snapshot of the cluster's health and state. It will also show any applications running in the cluster:

# How it works...

As you can see, the Service Fabric cluster is essential for creating and running applications created in Visual Studio. This will allow us to test applications directly on your local machine before publishing them to the cloud. As mentioned earlier, this isn't a watered-down version of the Service Fabric cluster. It is exactly the same version that would be installed on any one of the machines that you would install your Service Fabric applications on.

# Creating a Service Fabric application with a stateless actor service

As part of the introduction to this chapter, we looked at the difference between stateful and stateless microservices. The Service Fabric application templates available are then further divided into **Reliable Services** (stateful/stateless) and **Reliable Actors**. When to use which one is something that will depend on the specific business requirement of your application.

To put it simply though, if you wanted to create a service that should be exposed to many users of your application at any one time, a Reliable Service would probably be a good fit. Think of a service exposing the latest exchange rates that can be consumed by many users or applications at once.

Again, looking back to the introduction of this chapter, we used the example of an online web store with a shopping cart. A Reliable Actor could be a good fit for every customer buying items, so you could have a shopping cart actor. The Reliable Actor as part of the Service Fabric framework is based on the Virtual Actor pattern. Have a look at the article on the Virtual Actor pattern at <http://research.microsoft.com/en-us/projects/orleans/>.

To show you how easy it is to create a microservice using a stateless actor service as an example, we will use Visual Studio to publish a service to the Service Fabric cluster and call that service from a console (client) application.

# Getting ready

To complete this recipe, you must ensure that you have installed your local Service Fabric cluster on your local machine. You also need to ensure that the Azure Development and Management workload in Visual Studio 2017 has been installed. Enable this workload when you install Visual Studio 2017. If you did not install the workload as part of Visual Studio 2017, you can do so by clicking on the Web Platform Installer for Visual Studio 2017 and maintaining the installation.

```
namespace UtilitiesActor.Interfaces <br/> { <br/> public interface IUtilitiesActor : IActor <br/> { <br/> Task<bool> ValidateEmailAsync(string emailToValidate); <br/> } <br/> }

namespace UtilitiesActor <br/> { <br/> internal class UtilitiesActor : StatelessActor, IUtilitiesActor <br/> { <br/> public UtilitiesActor(ActorService actorService, <br/> ActorId actorId) : base(actorService, actorId)<br/> {<br/> }<br/> public async Task<bool> ValidateEmailAsync(string <br/> emailToValidate) <br/> { <br/> throw new NotImplementedException(); <br/> } <br/> } <br/>

public async Task<bool> ValidateEmailAsync(string emailToValidate)<br/> {<br/>
ActorEventSource.Current.ActorMessage(this, "Email Validation");<br/> return await Task.FromResult(Regex.IsMatch(emailToValidate, <br/> @"A(?:[a-z0-9!#$%&'*+=?^_&grave;{|}~]+(?:[<br/> a-z0-9!#$%&'*+=?^_&grave;{|}~]+)*@(?:[a-z0-9](?:[a-z0-9-]<br/> *[a-z0-9])?.)+[a-z0-9](?:[a-z0-9-]*[a-z0-9])?)<br/> Z",
 RegexOptions.IgnoreCase));<br/> }
```

```
namespace sfApp.Client <br/> { <br/> class Program <br/> { <br/> static void Main(string[] args)<br/> {<br/> var actProxy = ActorProxy.Create<IUtilitiesActor><br/>(ActorId.CreateRandom(), "fabric:/sfApp");<br/> WriteLine("Utilities Actor {0} - Valid Email?:{1}", <br/> actProxy.GetActorId(), actProxy.ValidateEmailAsync(<br/>"validemail@gmail.com").Result);<br/> WriteLine("Utilities Actor {0} - Valid Email?:{1}", <br/> actProxy.GetActorId(), actProxy.ValidateEmailAsync(<br/>"invalid@email@gmail.com").Result);<br/> ReadLine();<br/> } <br/> } <br/>
```

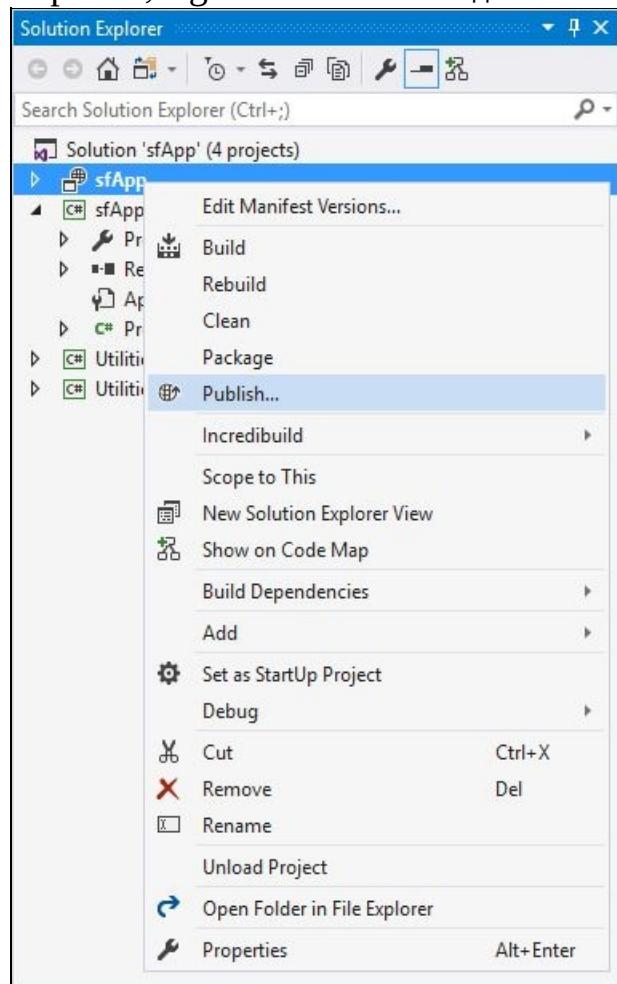

```
using Microsoft.ServiceFabric.Actors;<br/> using Microsoft.ServiceFabric.Actors.Client; <br/> using UtilitiesActor.Interfaces;<br/> using static System.Console;
```

All we are doing is creating a proxy for our actor and writing the output of the e-mail validation to the console window. Your client application is now ready.

# How it works...

Before we can run the client application, however, we need to publish our service first. In Solution Explorer, right-click on the `sfApp` service and click on Publish... from the context menu:

The Publish Service Fabric Application window will now be displayed. Click on the Select... button next to the Connection Endpoint textbox. Select Local Cluster as your Connection Endpoint and click on OK. Change Target profile and Application Parameters File to `Local.1Node.xml`. When you are done, click on the

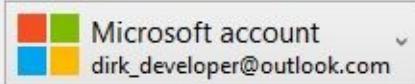

## Publish Service Fabric Application

_Node_3	localhost	NodeType3	3
_Node_4	localhost	NodeType4	4

You are now ready to run your client application. Right-click on the `sfApp.Client` project and select Debug and Start new instance from the context menu. The console application calls the `validate` method to check the e-mail addresses and displays the results to the console window. The results are as expected:

```
C:\sc\Microservices\sfApp.Client\bin\x64\Debug\sfApp.Client.... Utilities Actor -5742697865592686847 - Valid Email?:True Utilities Actor -5742697865592686847 - Valid Email?:False
```

If you receive a `System.BadImageFormatException` when trying to run your console application,

*check to see what platform your console application is targeting. You might have compiled your console application as Any CPU while the other projects in your solution target x64. Modify this from the Configuration Manager and make the console application also target x64.*

We can, however, be more specific when creating the actor ID. In the previous code listing, we used the `CreateRandom()` method to generate an `ActorId`. We can now give it a specific name. Modify your proxy code and create a new `ActorId` instance and give it any string value. In the following code listing, I just called mine `utilities`:

```
var actProxy = ActorProxy.Create<IUtilitiesActor>(new ActorId("Utilities"), "fabric:/sfApp");
```

*The `ActorId` method can take a parameter of type `Guid`, `long`, or `string`.*

When you debug your client application again, you will notice that `utilities` now has a logical name (the same name you passed as string value when creating a new `ActorId` instance):

```
C:\sc\Microservices\sfApp.Client\bin\x64\Debug\sfApp.Client.... - X
Utilities Actor Utilities - Valid Email?: True
Utilities Actor Utilities - Valid Email?: False
```

Creating your Service Fabric application and publishing it locally is a perfect solution for testing your application before publishing it to the cloud. Creating small, independent microservices allows developers many benefits related to testing, debugging, and deploying efficient and robust code that your applications can leverage to ensure maximum availability.

# Using Service Fabric Explorer

There is another tool that you can use to visualize the Service Fabric cluster. It is a standalone tool that you can find by navigating to the local installation path at %Program Files%\Microsoft SDKs\Service Fabric\Tools\ServiceFabricExplorer and clicking on ServiceFabricExplorer.exe. When you run the application, it will automatically connect to your local Service Fabric cluster. It can display rich information regarding the applications on the cluster, the cluster nodes, health status of the applications and nodes, and any load on the applications in the cluster.

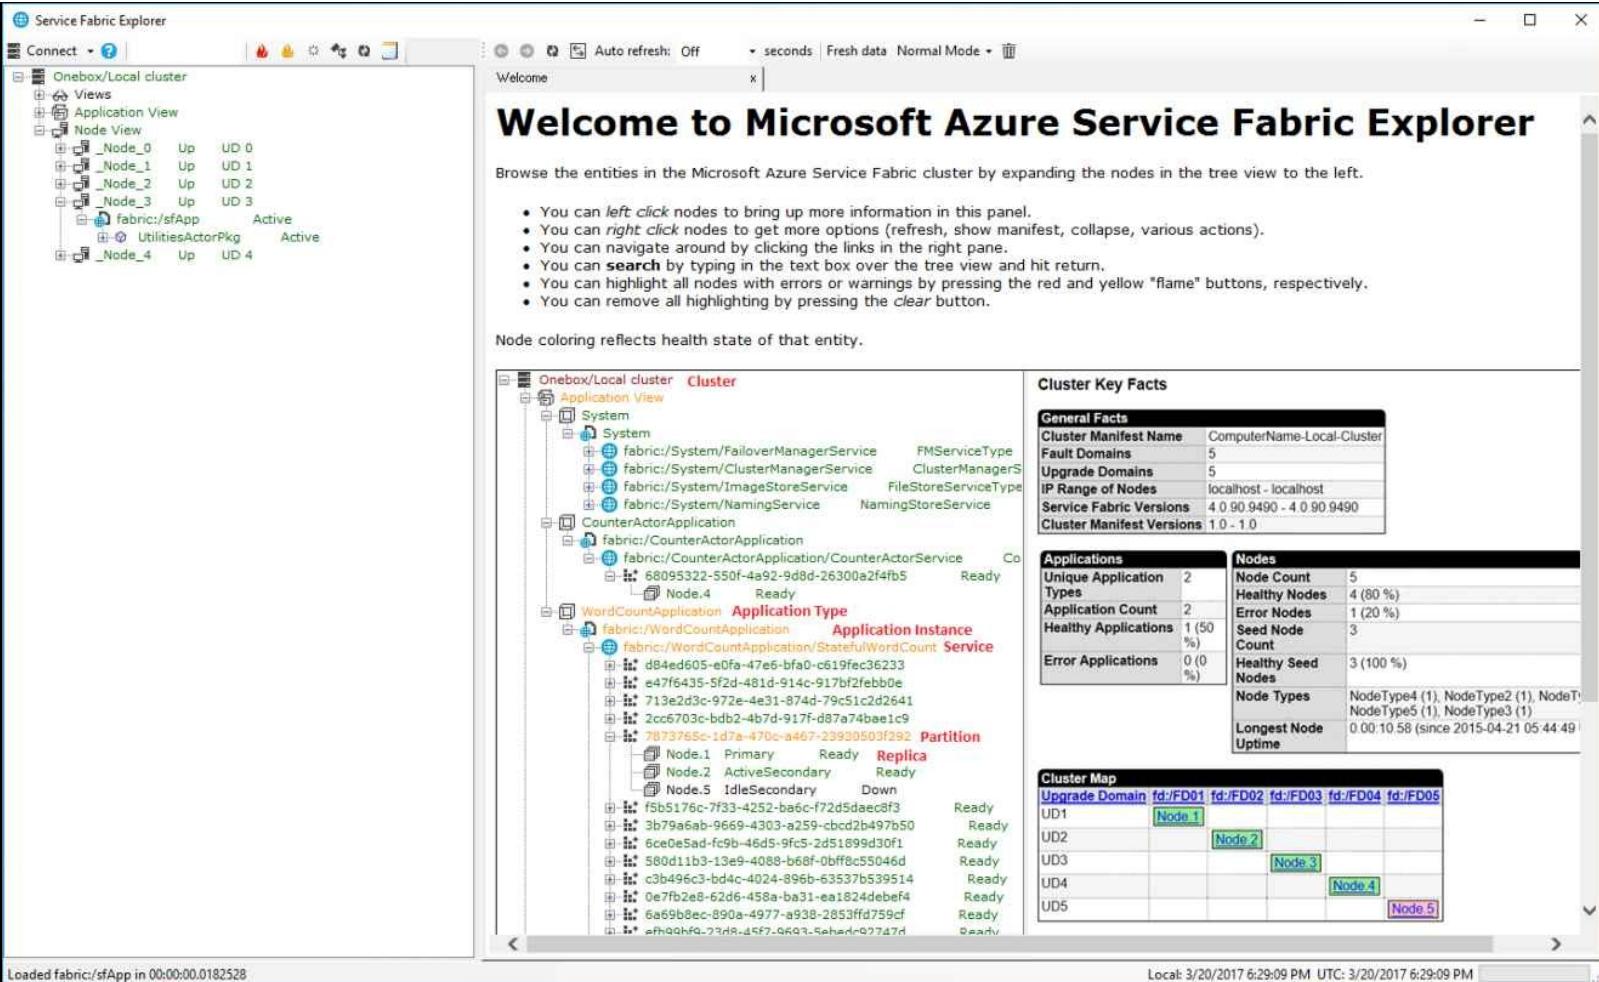

# Getting ready

You must have already completed the installation of Service Fabric on your local machine for Service Fabric Explorer to work. If you have not done so yet, follow the *Downloading and installing Service Fabric* recipe in this chapter.

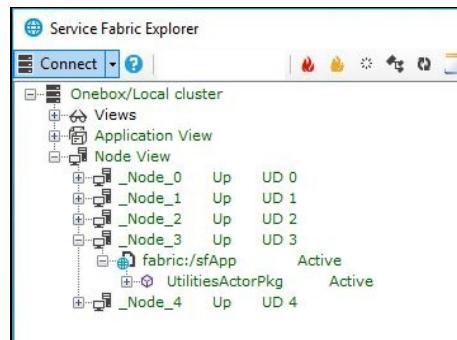

# How to do it...

1. When you start Service Fabric Explorer, the following window will appear:

2. Note that the tree view to the left displays Application View and Node View:

3. The pane on the right-hand side will display information regarding the local cluster. This makes it easy for you to see the overall health of the local Service Cluster:

Onebox/Local cluster

### Cluster 'Onebox/Local cluster'

#### Cluster Health

Aggregated health state **Ok**

Property	Health	Description	SourceUtc	LastModifiedUtc	Expired	Sourceld	TTL	Del on Exp	Sequence #
New health report									

#### Cluster Key Facts

General Facts	
Cluster Manifest Name	ComputerName-Local-Cluster
Fault Domains	5
Upgrade Domains	5
IP Range of Nodes	localhost - localhost
Service Fabric Versions	5.4.164.9494 - 5.4.164.9494
Cluster Manifest Versions	1.0 - 1.0

Applications		Nodes	
Unique Application Types	1	Node Count	5
Application Count	2	Healthy Nodes	5 (100 %)
Healthy Applications	2 (100 %)	Error Nodes	0 (0 %)
Error Applications	0 (0 %)	Seed Node Count	3
		Healthy Seed Nodes	3 (100 %)
		Node Types	NodeType4 (1), NodeType3 (1), NodeType2 (1), NodeType1 (1), NodeType0 (1)
		Longest Node Uptime	1.07:46.39 (since 2017-03-19 10:46:14 UTC)

Node Deactivations					
Name	UD	Status	EffectiveIntent	DeactivationStatus	DeactivationTasks
SafetyChecks					
<b>Cluster Map</b>					
Upgrade Domain	fd:/0	fd:/1	fd:/2	fd:/3	fd:/4
0	<span style="background-color: green;">Node_0</span>				
1		<span style="background-color: green;">Node_1</span>			
2			<span style="background-color: green;">Node_2</span>		
3				<span style="background-color: green;">Node_3</span>	
4					<span style="background-color: green;">Node_4</span>

- When you expand Application View, you will notice that our `sfApp` service has been published. Expanding it even further, you will see that the `sfApp` service has been published on Node\_3. Expand Node View and Node\_3 to see the service active on that node:

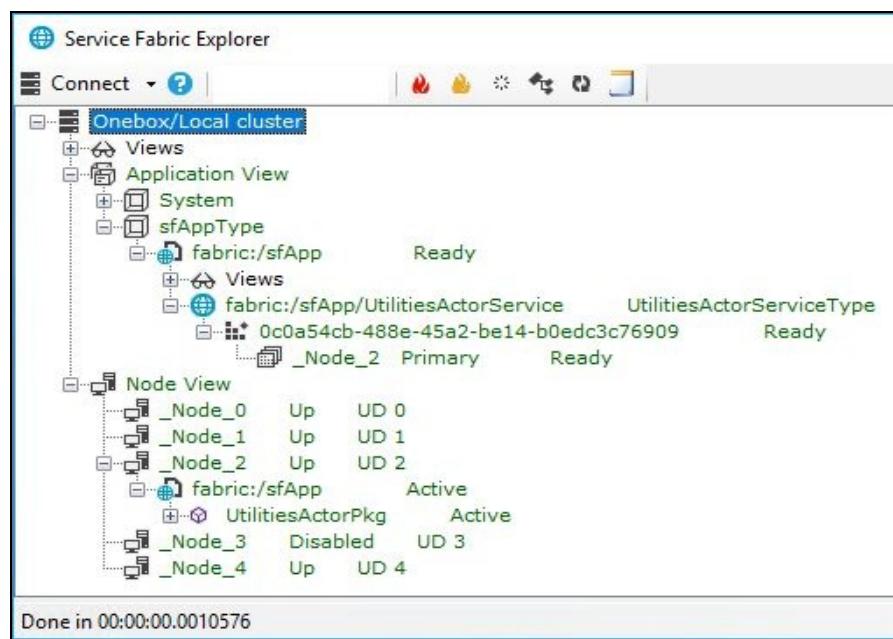

Service Fabric Explorer

Connect ? | 🔥 🔥 ⚡ ⚡ ⚡

- Onebox/Local cluster
  - Views
  - Application View
    - System
    - `sfAppType`
      - `fabric:/sfApp` Ready
        - Views
        - `fabric:/sfApp/UtilitiesActorService` UtilitiesActorServiceType

# How it works...

Service Fabric Explorer will allow you to see information on the selected node, and you will be able to drill down and see a rich amount of information regarding the Service Fabric cluster applications. It just another utility for administrators to use apart from the Service Fabric Explorer available in the browser.

There is some heated debate as to the manner in which developers should approach the microservices architecture. There are some that believe that when your goal as a developer is a microservices architecture for your application, you need to approach it from a monolith-first perspective. That is to say, write the big monolithic application first because that process is a familiar approach to development. After you have done that, plan and carve up the monolithic application into smaller microservices. The argument here is that the time to market is much quicker when creating a monolithic application. A quicker time to market means a quicker return on your investment.

Then the other side of the argument is that starting with a monolith is exactly the wrong approach to follow. The correct time to start thinking about how to carve up your application into pieces is at the design phase. The concession is made, however, that the development team will probably need to understand the system they are required to build. Another concession is made in the fact that it would probably be better to start off with a microservices approach when creating a second version of the existing monolith. A monolithic application by definition has all the parts tightly coupled to each other. How much time would it take to break these into smaller microservices?

Whichever approach you decide to take, it is one that must be decided on after careful consideration of all the facts involving all the stakeholders. Unfortunately, there is no formula or hard and fast rule to aid you in your decision. The decision regarding architecture of an application (monolithic versus microservices) will vary from project to project.

# Azure and Serverless Computing

Right about now, I bet that there are some of you coming to this chapter asking, "What does serverless computing even mean?" The name is confusing, I agree. It makes no sense (to me anyway), but when you understand the concept it kind of makes sense. In this chapter, we will have a look at what the term Serverless Computing means. We will also take a look at:

- Creating an Azure Function
- Providing print functionality with DocRaptor
- Using AWS and S3
- Creating C# lambda functions with AWS

# Introduction

Serverless does not mean the lack of a server, but rather you (or the application) does not know which server is used to provide some functionality to an application. Serverless, therefore, describes an application that depends on some 3rd party app or service that lives in the cloud to provide some logic or functionality to the application.

Let us use the example of a student research portal. Students research a certain topic and create documents in the portal related to what they need to research. They can then load print credits against their profile and print the saved documents they need. After a page is printed, the print credit is deducted from their profile.

While this is a very simple example, I am using it to illustrate the concept of serverless computing. We can split the application up into various components. These are as follows:

1. Login authentication
2. Purchasing print credits
3. Updating remaining print credits
4. Printing documents

*There could be several other components required not mentioned here, but this is not the real world. We are just creating this hypothetical application to illustrate the concept of serverless computing.*

Why write the code to provide login authentication in your application when there are already third-party services out there that do just that? Similarly, why write code to print documents when there are services that provide quite rich functionality you can just consume in your application? Anything specific such as the purchasing and loading of student print credits, can be created using an Azure Function. The topic of serverless computing is broad and still in its infancy. There is much to learn and experience. Let's take the first steps and explore what benefits this can have for developers.

# Creating an Azure function

Why Azure Functions? Imagine that you have an application that needs to provide some specific functionality, but that still scales up when the call rate to your function increases. This is where Azure Functions provide a benefit. With Azure Functions, you only pay for the compute that your function needs at a specific instance in time, and it is immediately available.

To get started, head on over to <https://azure.microsoft.com/en-us/services/functions> and create a free account.

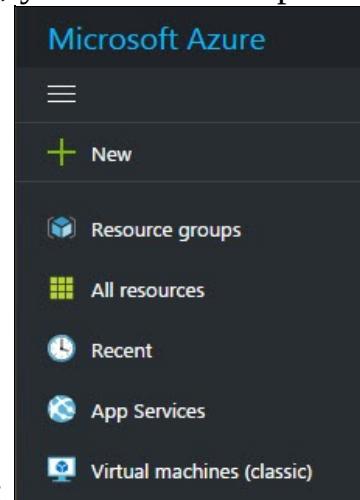

*Because you only pay for the actual computing time you use when running Azure Functions, it is imperative that your code is as optimized as possible. If you refactor the Azure Function code and gain a 40% code execution improvement, you are directly saving 40% in your monthly expense. The more you refactor and improve your code, the more money you will save.*

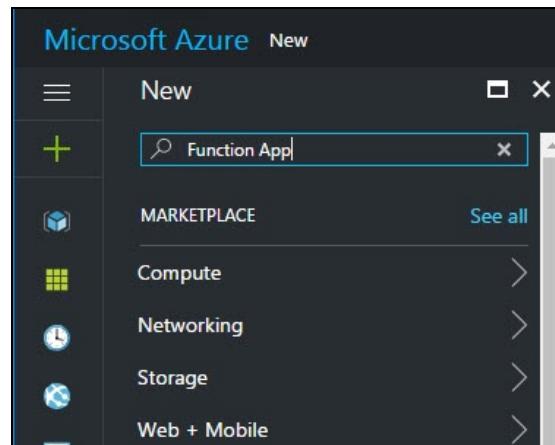

# Getting ready

You need to have an Azure account set up. If you don't have one, you can set one up for free. From the

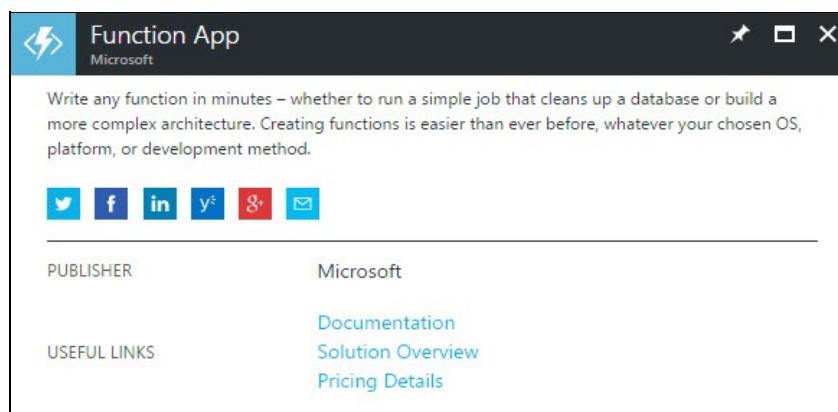

Azure portal, on the left-side menu, click on New to get started:

In the search box, type in `Function App` and hit the *Enter* button. The first result should be Function App. Select that.

When you select the Function App, you will see this screen pop out to the right. The description perfectly describes what Azure Functions do. Click the Create button at the bottom of this form.

You now see a form that allows you to give your function a name and select the Resource Group and other settings. Click on the Create button when you are done.

Function App

\* App name  
funcCredit .azurewebsites.net

\* Subscription  
Visual Studio Ultimate with MSDN

\* Resource Group ⓘ  
 Create new  Use existing  
Default-ApplicationInsights-CentralUS

\* Hosting Plan ⓘ  
Consumption Plan

\* Location  
UK South

\* Storage Account  
functione3a399efb592 >

# How to do it...

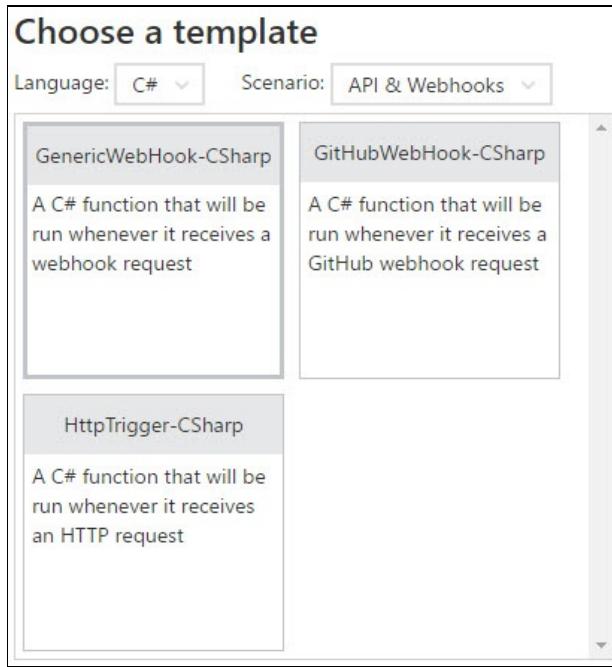

1. After Azure has created the new Function App, you will then be able to create an Azure Function. All that we are going to do is to create an Azure Function that will be triggered whenever something happens on a GitHub repository. Click on the Create your own custom function link.

The screenshot shows the Microsoft Azure Functions landing page. The top section has a blue header with the title "The faster way to functions" and subtext: "Write any function in minutes - whether to run a simple job that cleans up a database or to build a more complex architecture. Creating functions is easier than ever before, whatever your chosen OS, platform, or development method. No install required." To the right is a graphic of a lightning bolt inside a circle with two databases. Below the header, there's a section titled "Get started quickly with a premade function". It includes a step 1: "Choose a scenario:" with three options: "Timer" (clock icon), "Data processing" (database icon, highlighted with a blue border), and "Webhook + API" (code editor icon). Step 2: "Choose a language:" offers "C#" and "JavaScript". At the bottom is a large blue "Create this function" button.

*According to the Microsoft Azure site, the following are supported when writing Azure Functions: JavaScript, C#, F#, and scripting options such as Python, PHP, Bash, Batch, and PowerShell.*

2. You will now see that you are given a choice between several templates. Choose C# from the Language selection and API & Webhooks from the Scenario selection and then select the GitHubWebHook-CSharp template. Azure will now ask you to give your function a name. I called mine `GithubAzureFunctionWebHook`. Click on the Create button to create the function.

3. When your function is created, you will see that it has added some default code for you in the online code editor.

```
using System.Net;

public static async Task<HttpResponseMessage> Run
    (HttpRequestMessage req, TraceWriter log)
{
    log.Info("C# HTTP trigger function processed a request.");

    // Get request body
    dynamic data = await req.Content.ReadAsAsync<object>();

    // Extract github comment from request body
    string gitHubComment = data?.comment?.body;

    return req.CreateResponse(HttpStatusCode.OK, "From Github:" +
        gitHubComment);
}
```

4. Preceding the `return` statement, add the following line of code: `log.Info($"Message from GitHub: {gitHubComment}");`. This is so that we will see what was sent from GitHub.
5. Your code should now look as follows. Note that there are two links that allow you to get the function URL and the GitHub secret. Click on those links and copy the values of each to Notepad. Click on the Save and run button.

Your Azure Function URL should be something like:  
<https://funccredits.azurewebsites.net/api/GithubAzureFunctionWebHook>

run.csx

Save

▶ Save and run

</> Get function URL </> Get GitHub secret

```
1 using System.Net;
2
3 public static async Task<HttpResponseMessage> Run(HttpRequestMessage req, TraceLog log)
4 {
5     log.Info("C# HTTP trigger function processed a request.");
6
7     // Get request body
8     dynamic data = await req.Content.ReadAsAsync<object>();
9
10    // Extract github comment from request body
11    string gitHubComment = data?.comment?.body;
12    log.Info($"Message from GitHub: {gitHubComment}");
13
14    return req.CreateResponse(HttpStatusCode.OK, "From Github:" + gitHubComment);
15 }
```

6. Head on over to GitHub at <https://github.com/>. If you don't have an account, create one and create a repository (GitHub is free for open source projects). Go to the repository you created, and click on the Settings tab. To the left, you will see a link called Webhooks. Click on that link.

The screenshot shows the GitHub repository settings page for 'dirkstrauss / Extension-Methods'. The 'Settings' tab is selected. On the left, there's a sidebar with links: Options, Collaborators, Branches, Webhooks (which is highlighted), Integrations & services, and Deploy keys. The main area has two sections: 'Repository name' (set to 'Extension-Methods') with a 'Rename' button, and 'Features' (with 'Wikis' checked).

7. You will now see a button to the right called Add webhook. Click on that button.

[Code](#)[Issues 0](#)[Pull requests 0](#)[Projects 0](#)[Wiki](#)[Pulse](#)[Graphs](#)[Settings](#)[Options](#)[Collaborators](#)[Branches](#)[Webhooks](#)[Integrations & services](#)[Deploy keys](#)

## Webhooks

[Add webhook](#)

Webhooks allow external services to be notified when certain events happen within your repository. When the specified events happen, we'll send a POST request to each of the URLs you provide. Learn more in our [Webhooks Guide](#).

8. Add the Azure Function URL you copied earlier to the Payload URL field. Change the Content type to application/json and add the GitHub secret you copied earlier to the Secret field. Select Send me everything and click on the Add webhook button.

Webhooks / Add webhook

We'll send a POST request to the URL below with details of any subscribed events. You can also specify which data format you'd like to receive (JSON, x-www-form-urlencoded, etc). More information can be found in our [developer documentation](#).

**Payload URL \***

**Content type**

**Secret**

By default, we verify SSL certificates when delivering payloads. [Disable SSL verification](#)

**Which events would you like to trigger this webhook?**

Just the push event.  
 Send me everything.  
 Let me select individual events.

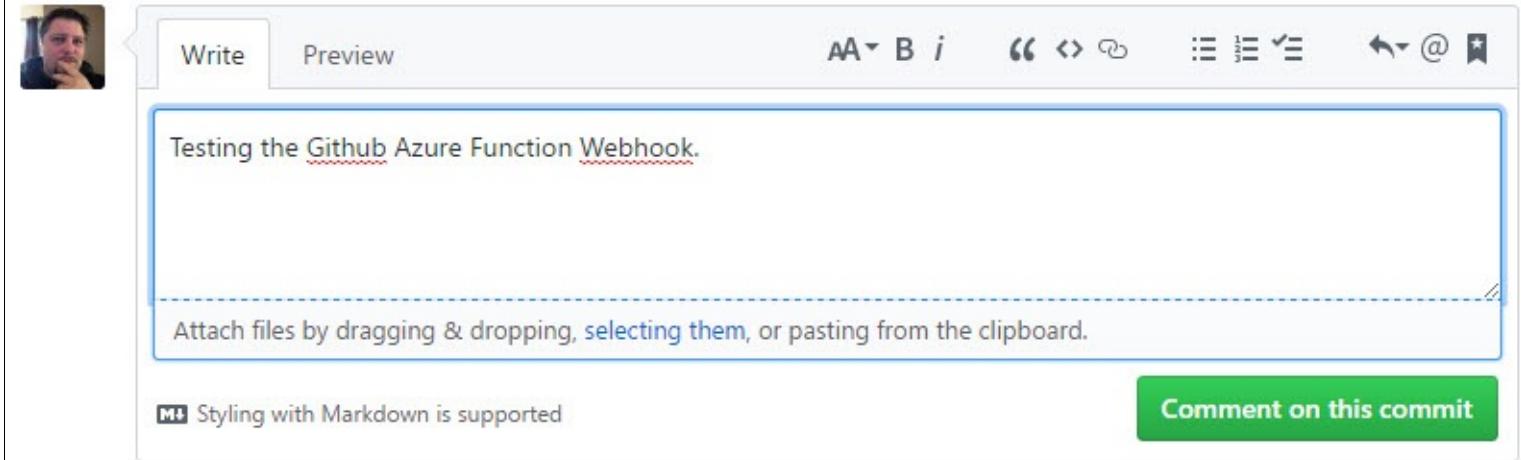

Active  
We will deliver event details when this hook is triggered.

**Add webhook**

# How it works...

Still in your GitHub repository, open a file and add a comment to it. Click on the Comment on this commit button.

The screenshot shows the GitHub commit interface. A user profile picture is in the top-left corner. Below it, there are two tabs: "Write" (selected) and "Preview". To the right are various editing tools like font size, bold, italic, and code blocks. A large text area contains the comment: "Testing the Github Azure Function Webhook.". Below the text area is a dashed line, followed by a note: "Attach files by dragging & dropping, selecting them, or pasting from the clipboard." At the bottom left, a note says "Styling with Markdown is supported". On the bottom right is a green button labeled "Comment on this commit".

Swing back to your Azure Function and take a look at the Logs window. This window is directly below the code window. You will see that the comment we posted in GitHub pops up in the log output of the Azure Function.

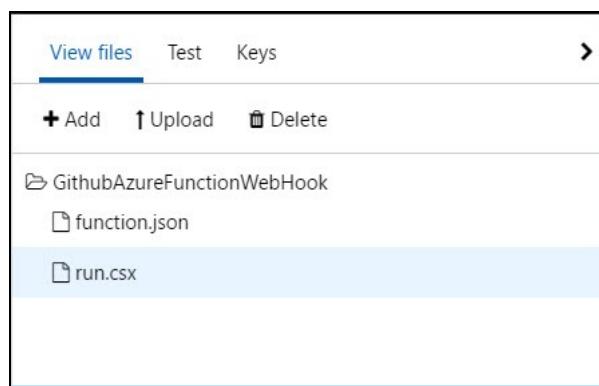

The screenshot shows the Azure Function Logs window. At the top, there are buttons for "Logs", "Pause", "Clear", "Copy logs", and "Expand". The main area displays the log output:

```
2017-03-01T20:16:22.565 C# HTTP trigger function processed a request.  
2017-03-01T20:16:22.565 Message from GitHub: Testing the Github Azure Function Webhook.  
2017-03-01T20:16:22.565 Function completed (Success, Id=bc9a4221-bcae-457e-ae56-3d256d9);
```

*If nothing appears in the log window, ensure that you have clicked on the Run button of the Function. If all else fails, click on the Run button at the bottom of the Test window.*

While this is a very simple example, the usefulness of Azure Functions should become evident to you. You will also notice that the function has a .csx extension. What is important to note is that Azure Functions share a few core concepts and components irrespective of which programming language you choose to code it in. At the end of the day, a function is the primary concept here. You also have a `function.json` file that contains JSON configuration data. You can see this and other files by clicking on the View files link to the right.

Clicking on the `function.json` file, you will see the contents of the JSON file. Changing the `disabled` property to `true` will effectively stop the function from executing if called. You will also notice the `bindings` property. Here, you configure your web hook. All these settings can be set from within the Integrate and other sections of the Azure Function.

```
{
  "bindings": [
    {
      "type": "httpTrigger",
      "direction": "in",
      "webHookType": "github",
      "name": "req"
    },
    {
      "type": "http",
      "direction": "out",
      "name": "res"
    }
  ],
  "disabled": false
}
```

Azure Functions and the benefits exposed to developers is an exciting concept. This is one area of your programming repertoire that will surely keep you busy for many hours as you explore more intricate and complex tasks.

# Providing print functionality with DocRaptor

Printing from a web application has always been tricky. This is much easier these days with the availability of numerous third-party controls that provide print functionality to your application. The reality, however, is that I have come across many projects where, when they were developed, used a third-party control to provide print functionality. At the time it was developed, the third-party control was good and did exactly what they needed.

Having this functionality available to the application means that the companies that purchase the licenses for these third-party controls, rarely continue renewing their licenses. Within a few years, however, this results in a web application that contains old and dated print technology. While there is nothing wrong with this, it does have some drawbacks.

The developers are usually stuck with maintaining an aging code base, which is locked into this third-party control. Any change in requirements, and you'll find that developers are faced with making code work within the limitations of the third-party controls. Alternatively, they need to approach the powers that be and suggest that the third-party controls be updated to the latest version. This means that the small change needed in the print module, turns out to be more costly than anyone had budgeted.

 *Real world: I used to work for a company that would have consultants quote customers on what a change to some application functionality would cost. After the quote was given and accepted, it was handed to development to make it work within the allotted time frame and budget. This resulted in developers having to hack code to make it work and meet budget and deadlines because of a lack of proper project management skills. Replacing third-party controls would be virtually impossible because the budget was already set without input from development.*

I agree that there are some developers that do a very good job of providing and maintaining functionality in an aging code base. I also really love third-party controls and the functionality they provide. There are a select few big players that a developer can choose from. But here is the catch: why purchase a suite of third-party controls, when all you need is the ability to print an invoice for example? Using this logic, serverless make much more sense in many cases (this one included).

# Getting ready

This example will take a look at a service called DocRaptor. The service isn't free, but consider the cost of writing and maintaining code to provide print functionality in your web application. Consider the cost of buying third-party controls to provide the same functionality. It all comes down to what makes the most sense for you as a developer.

Create a basic web application and go to Tools, NuGet Package Manager, Package Manager Console. Type the following command in the console to install the DocRaptor NuGet package.

```
| Install-Package DocRaptor
```

Once DocRaptor is installed, you can head on over to their web page (<http://docraptor.com/>) to read through some of the API documentation or you can also swing by the GitHub page (<https://github.com/DocRaptor/docraptor-csharp>) for additional information.

*It will be better to have a look at the source code accompanying this book in order to copy the code for this recipe.*

```
<%@ Page Language="C#" AutoEventWireup="true" CodeBehind="InvoicePrint.aspx.cs" Inherits="Serverless.InvoicePrint" %><br/><br/> <!DOCTYPE html><br/><br/> <html xmlns="http://www.w3.org/1999/xhtml"><br/> <head runat="server"><br/> <title>Invoice</title><br/> <meta http-equiv="content-type" content="text/html;<br/> charset=utf-8"/><br/> <link href="css/invoice.css" rel="stylesheet" /><br/> <script type="text/javascript"><br/> function ToggleErrorDisplay()<br/> {<br/> if ($("#errorDetails").is(":visible")) {<br/> $("#errorDetails").hide();<br/> } else {<br/> $("#errorDetails").show();<br/> }<br/><br/> function TogglePrintResult() {<br/> if ($("#printDetails").is(":visible")) {<br/> $("#printDetails").hide();<br/> } else {<br/> $("#printDetails").show();<br/> }<br/> }<br/> </script><br/> </head><br/> <body><br/> <form runat="server"><br/> <div id="container"> <br/> <div id="main"><br/> <div id="header"><br/> <div id="header_info black">The Software Company<br/> <span class="black">|</span> (072)-412-5920 <br/> <span class="black">|</span> software.com</div><br/> </div><br/> <h1 class="black" id="quote_name">Invoice INV00015</h1><br/> <div id="client" style="float: right"><br/> <div id="client_header">client:</div><br/> <p class="address black"><br/> Mr. Wyle E. ```

# How it works...

Run your web application and see the basic invoice displayed on the web page. Make sure that you have set your `InvoicePrint.aspx` page as the start page for your web application. Click on the Print this invoice link.

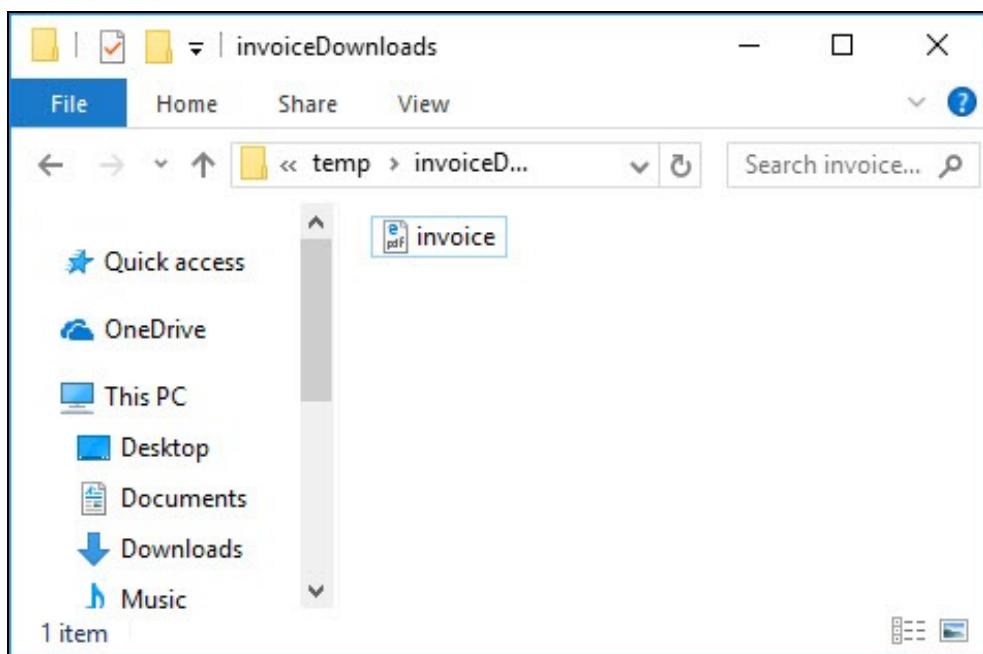

The screenshot shows a web browser window titled "Invoice". The address bar displays "localhost:37464/InvoicePr". The page content includes the company information "The Software Company | (072)-412-5920 | software.com", the invoice header "Invoice INV00015", and the client information "client: Mr. Wyle E. Coyote". Below this is a table of items with their descriptions and prices. At the bottom, there is a link "Print this invoice".

Stock Code	Item Description	price
BCR902I45	Acme Company Roadrunner Catch'em Kit Booster Skates Emergency Parachute	\$300 \$200 \$100
BFT547J78	Very Sneaky Trick Seed Kit Giant Magnet and Lead Roadrunner Seeds Rollerblades	\$800 \$500 \$300

TOTAL: \$1100

[Print this invoice](#)

You will see that the invoice is created in the output path you specified.

Click on the PDF document to open the invoice.

A screenshot of the Foxit Reader application window. The title bar says 'invoice.pdf - Foxit Reader'. The menu bar includes File, Home, Comment, View, Form, Protect, Share, Connect, Help, Extras, and a toolbar with various icons. The main content area displays an invoice. The header of the invoice reads 'Invoice INV00015'. Below the header, it says 'client: Mr. Wyle E. Coyote'. The invoice table has three columns: Stock Code, Item Description, and price. The first item is 'BCR902145' with 'Acme Company Roadrunner Catch'em Kit' and a breakdown of 'Booster Skates' (\$200), 'Emergency Parachute' (\$100), and a total of '\$300'. The second item is 'BFT547J78' with 'Very Sneaky Trick Seed Kit' and a breakdown of 'Giant Magnet and Lead Roadrunner Seeds' (\$500) and 'Rollerblades' (\$300), with a total of '\$800'. The total for the invoice is '\$1100'. The bottom of the window shows standard navigation and zoom controls.

DocRaptor provides a service that is really useful to developers creating web solutions. If you need to create PDF or Excel documents from your application, DocRaptor can benefit your team. The test document used in this example is free to use without it being deducted from your monthly quota (if you are

on a paid plan).

In the true serverless sense of the word, DocRaptor provides functionality to you without you having to write a lot of extra code. It is super easy to implement and super easy to maintain. The preceding example is really basic, but you can pass DocRaptor a URL instead of the `DocumentContent` to print the page you want. From the developer's perspective, they don't care how DocRaptor does what they do. It just works. And this is the idea behind serverless computing.

Developers can implement solutions in their applications easily, effortlessly, and in record time, using minimal code while adding a lot of value to the application they're developing. The functionality being implemented can also easily scale as demand increases. There are, however, overage charges on the professional plan. Lastly, creating a few PDF documents will probably not make much of a difference in server computing power. Consider then that DocRaptor is used by some large companies that probably generate thousands of documents each month. All those document generation requests do not get processed by the customer using DocRaptor, but by the DocRaptor servers themselves.

You are then left with being able to develop a lightweight, streamlined web application that will not place huge demand on your server as volumes increase.

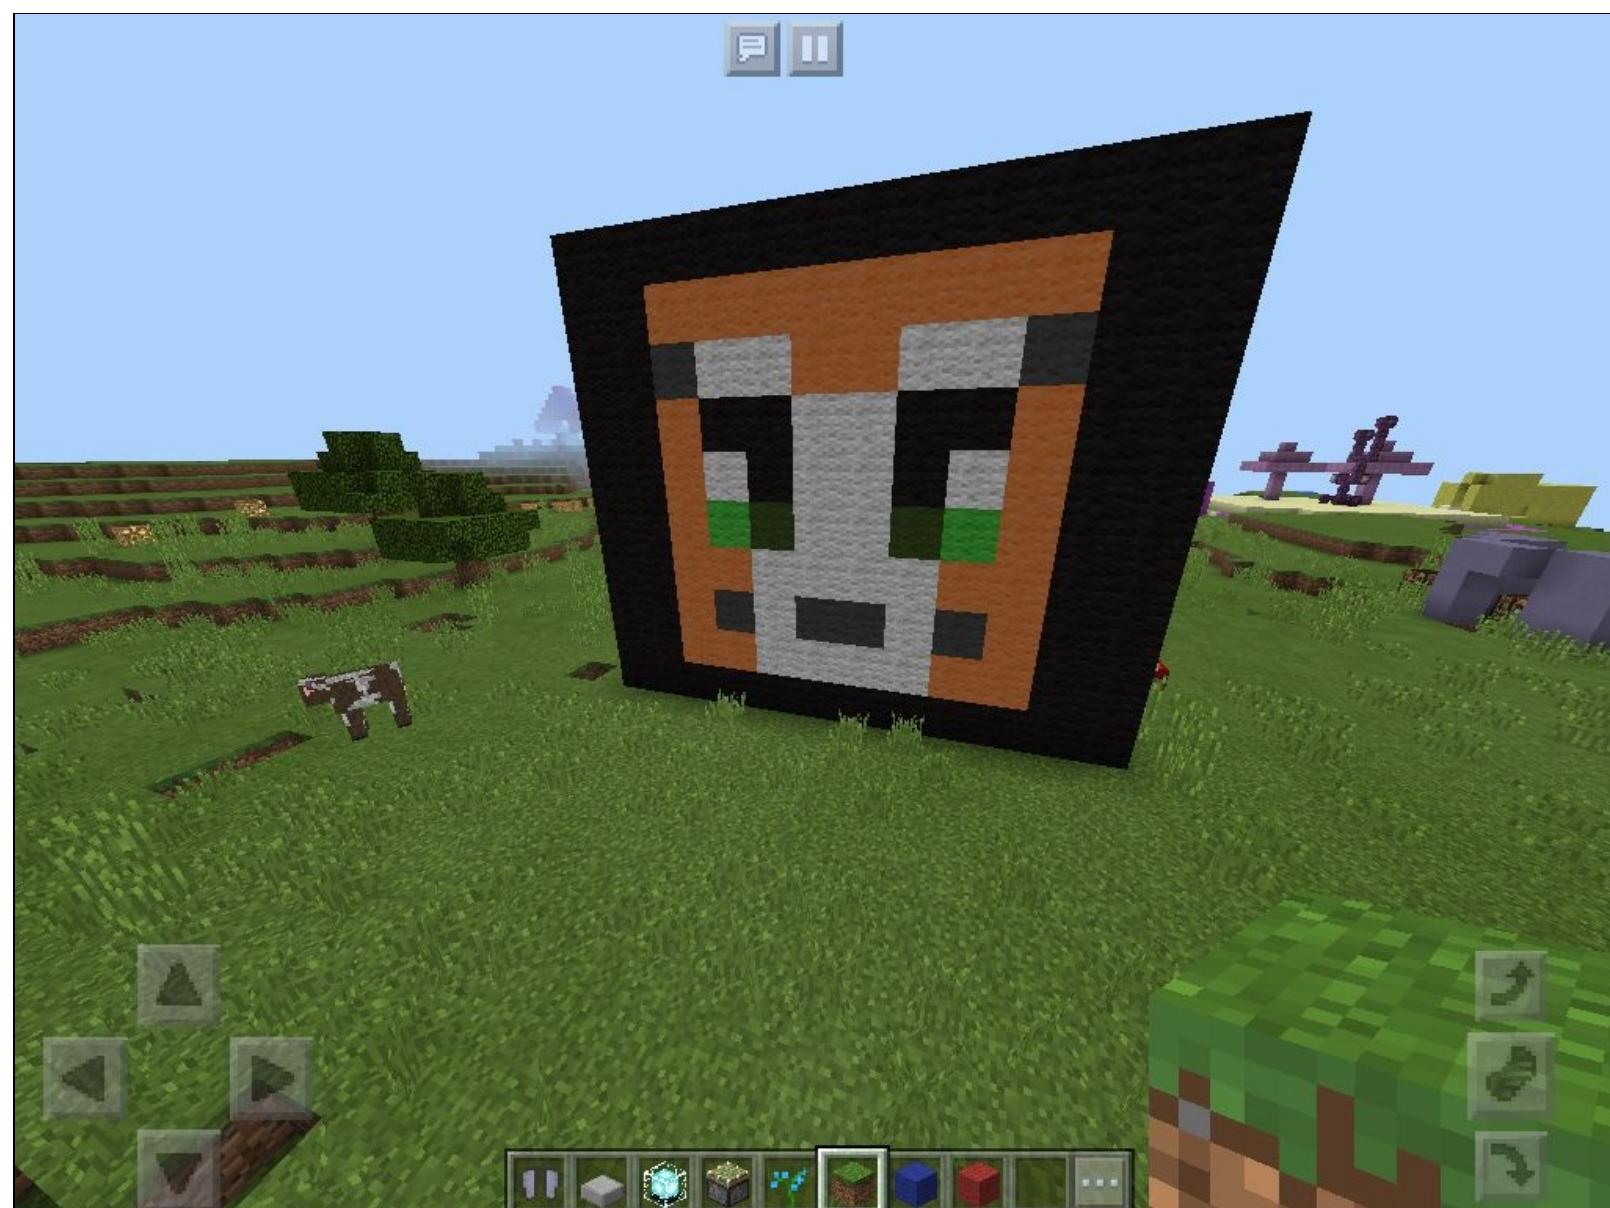

# Using AWS and S3

This chapter can't be considered complete without looking at Amazon Web Services (AWS). The topic of AWS is really vast. There is a lot of functionality provided by the platform. Developers can harness this in their applications and provide rich functionality with minimal code on their part. AWS also has really good documentation that developers can review to get up to speed quickly. S3 is Amazon's Simple Storage Service and allows you to store and retrieve data in the cloud.

I enjoy playing Minecraft with my kids. Some of the things they create are mind boggling, especially since my daughter (who plays as CupcakeSparkle) is 7 years old and my son (who plays as Cheetah) is only 4 years old. My daughter has been playing Minecraft since she was 5 and as you can imagine, she has created quite a few incredible structures. Joseph Garrett is by far my kids' favorite YouTuber who plays as Stampy Cat. They watch his Let's Play videos religiously (including Building Time with Squid Nugget). We often have Building Time competitions of our own and Stampy Cat and his lovely world serve as an inspiration for my kids in everything they do in Minecraft.

Here is the picture of Stampy Cat that my daughter built.

Here is the picture of Squid Nugget that my son built.

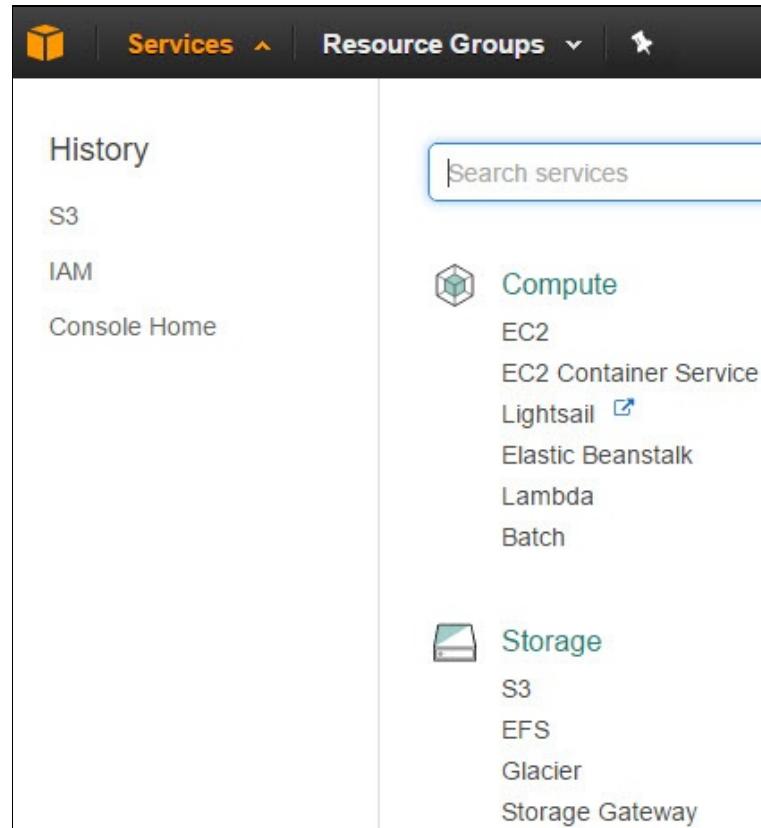

So, I want to create a place to upload some of their Minecraft pictures, screenshots, and other documents related to our Minecraft adventures. For this, we will use S3.

# Getting ready

This chapter assumes that you have signed up for an AWS account using the free tier. For more details regarding the free tier, navigate to <https://aws.amazon.com/free/>. One section I want to highlight though is the following: *"The Amazon Web Services (AWS) Free Tier is designed to enable you to get hands-on experience with AWS Cloud Services. The AWS Free Tier includes services with a free tier available for 12 months following your AWS sign-up date, as well as additional service offers that do not automatically expire at the end of your 12 month AWS Free Tier term."*

In order to sign up, you need to provide your credit card information. When the free tier period expires (or if your application exceeds the usage limitations), you will be charged the pay-as-you-go service rates. Regarding S3 specifically, the free tier allows 5GB of storage, 20,000 get requests and 2,000 put requests. First you will need to create an S3 bucket. From the Services selection, locate the Storage group and click on S3.

Create your first bucket. I named mine `familyvaultdocs` and selected the EU (Frankfurt) region. Click on Next until you have completed the creation of the bucket.

Create bucket X

1 Name and region    2 Set properties    3 Set permissions    4 Review

Name and region

Bucket name ?

Read, Write

Read, Write

## Manage public permissions

[Group](#)[i](#)[Object access](#)[i](#)[Permissions access](#)[i](#)

Everyone

Read, Write

Read, Write

Lastly, you will also need to create an access key and secret key for your application. From the Services, look for the Security, Identity & Compliance group and click on IAM (**Identity and Access Management**). Add a user with the Access type of Programmatic access. This will provide you with the access key ID and secret access key you need.

## Add user

Details

4

Complete

## Set user details

You can add multiple users at once with the same access type and permissions. [Learn more](#)

User name\*

 [Add another user](#)

## Select AWS access type

Select how these users will access AWS. Access keys and autogenerated passwords are provided in the last step. [Learn more](#)

Access type\*

**Programmatic access**

Enables an **access key ID** and **secret access key** for the AWS API, CLI, SDK, and other development tools.

**AWS Management Console access**

Enables a **password** that allows users to sign-in to the AWS Management Console.

With your bucket created, user permissions set to Everyone and access keys created, let's write some code.

```

internal static class StampyStampyWorld<br/> { <br/> public static void
SaveStampy(string fileToSave,<br/> string bucket,<br/> string bucketDirectory,<br/>
string bucketFilename)<br/> {<br/> IAmazonS3 client =
AWSClientFactory.CreateAmazonS3Client<br/> (RegionEndpoint.EUCentral1);<br/>
<br/> TransferUtility utility = new TransferUtility(client); <br/>
TransferUtilityUploadRequest request = new <br/> TransferUtilityUploadRequest();<br/>
<br/> request.BucketName = bucket + "/" + bucketDirectory;<br/> request.Key =
bucketFilename; <br/> request.FilePath = fileToSave; <br/> utility.Upload(request); <br/>
}<br/> }

static void Main(string[] args)<br/> {<br/> string uploadFile = "C:UsersdirkPicturesSaved
<br/> PicturesStampyCat.png";<br/> string S3Bucket = "familyvaultdocs"; <br/> string
S3Folder = "MinecraftPictures";<br/> string uploadedFilename = $""
{DateTime.Now.ToString("yyyyMMdd")}<br/> - StampyCat.png";<br/>
StampyStampyWorld.SaveStampy(uploadFile, S3Bucket, S3Folder,<br/>
uploadedFilename);<br/> WriteLine("uploaded");<br/> ReadLine();<br/> }

<?xml version="1.0" encoding="utf-8" ?><br/> <configuration><br/> <appSettings>
<br/> <add key="AWSProfileName" value="profile1"/><br/> <add
key="AWSAccessKey" value="AKIAJ6Q2Q77IHJX7STWA"/><br/> <add
key="AWSSecretKey" value="uFBN6xtuWCSf9zR9WzQKrh1vk<br/>
zU2PEuosTTy5qhc"/><br/> </appSettings><br/> <startup><br/> <supportedRuntime
version="v4.0" sku=".NETFramework,<br/> Version=v4.6.2" /><br/> </startup><br/>
</configuration>

```

5. Run your console application. After the file is uploaded, your console application will just display the text uploaded in the output.

# How it works...

Swing back to your `familyvaultdocs` bucket in AWS and click on the refresh icon next to the EU (Frankfurt) region. You will see the folder `MinecraftPictures` you specified in code.

Amazon S3 > familyvaultdocs

Objects Properties Permissions Management

Upload Create folder More All Deleted objects EU (Frankfurt)

Name	Last modified	Size	Storage class
MinecraftPictures	--	--	--

Viewing 1 to 1

Operations 0 In progress 1 Success 0 Error

Clicking on the folder, you will see the contents listed. I previously uploaded the `SquidNugget.png` image, but the `StampyCat.png` image we uploaded in our code sample has been prefixed with the date as specified in code.

The screenshot shows the AWS S3 console interface. At the top, there are navigation links for 'Services' (with a dropdown arrow), 'Resource Groups' (with a dropdown arrow), and a search bar. On the far right, there are icons for notifications and user profile.

The main area displays the 'Amazon S3 > familyvaultdocs > MinecraftPictures' path. Below this, there are four tabs: 'Objects' (selected), 'Properties', 'Permissions', and 'Management'. A search bar with a magnifying glass icon and placeholder text 'Type a prefix and press Enter to search. Press ESC to clear.' is located below the tabs.

Below the search bar are several action buttons: 'Upload' (with an upward arrow icon), 'Create folder' (with a plus sign and folder icon), 'More' (with a dropdown arrow), and two buttons labeled 'All' and 'Deleted objects' (the latter is highlighted). To the right of these buttons, it says 'EU (Frankfurt)' and 'Viewing 1 to 2'.

The main content area is a table listing the objects in the folder:

<input type="checkbox"/>	Name	Last modified	Size	Storage class
<input type="checkbox"/>	20170012 - StampyCat.png	Mar 12, 2017 2:00:02 PM	613.1 KB	Standard
<input type="checkbox"/>	20175912 - SquidNugget.png	Mar 12, 2017 1:59:39 PM	587.7 KB	Standard

At the bottom of the table, it says 'Viewing 1 to 2'.

The code is run and the files are added almost immediately. Admittedly they aren't very big files, but this goes to show how easy it is to add a simple storage service to AWS and integrate that with a .NET application.

# Creating C# Lambda functions with AWS

On the 1st of December 2016, Amazon announced that C# was now a supported language for AWS Lambda. This is therefore really fresh off the press, so to speak, and developers can experiment with using AWS Lambda in their .NET applications. AWS Lambda allows you to deploy your code to AWS and not have to worry about the machines the code runs on or even worry about the scaling of those machines when demand increases. Your code will just work. This is really great for mobile developers. Up until December, AWS Lambda only supported Node.js, Pythos, and Java. Let's take a look at how to create a Lambda function in Visual Studio 2017 using C#.

# Getting ready

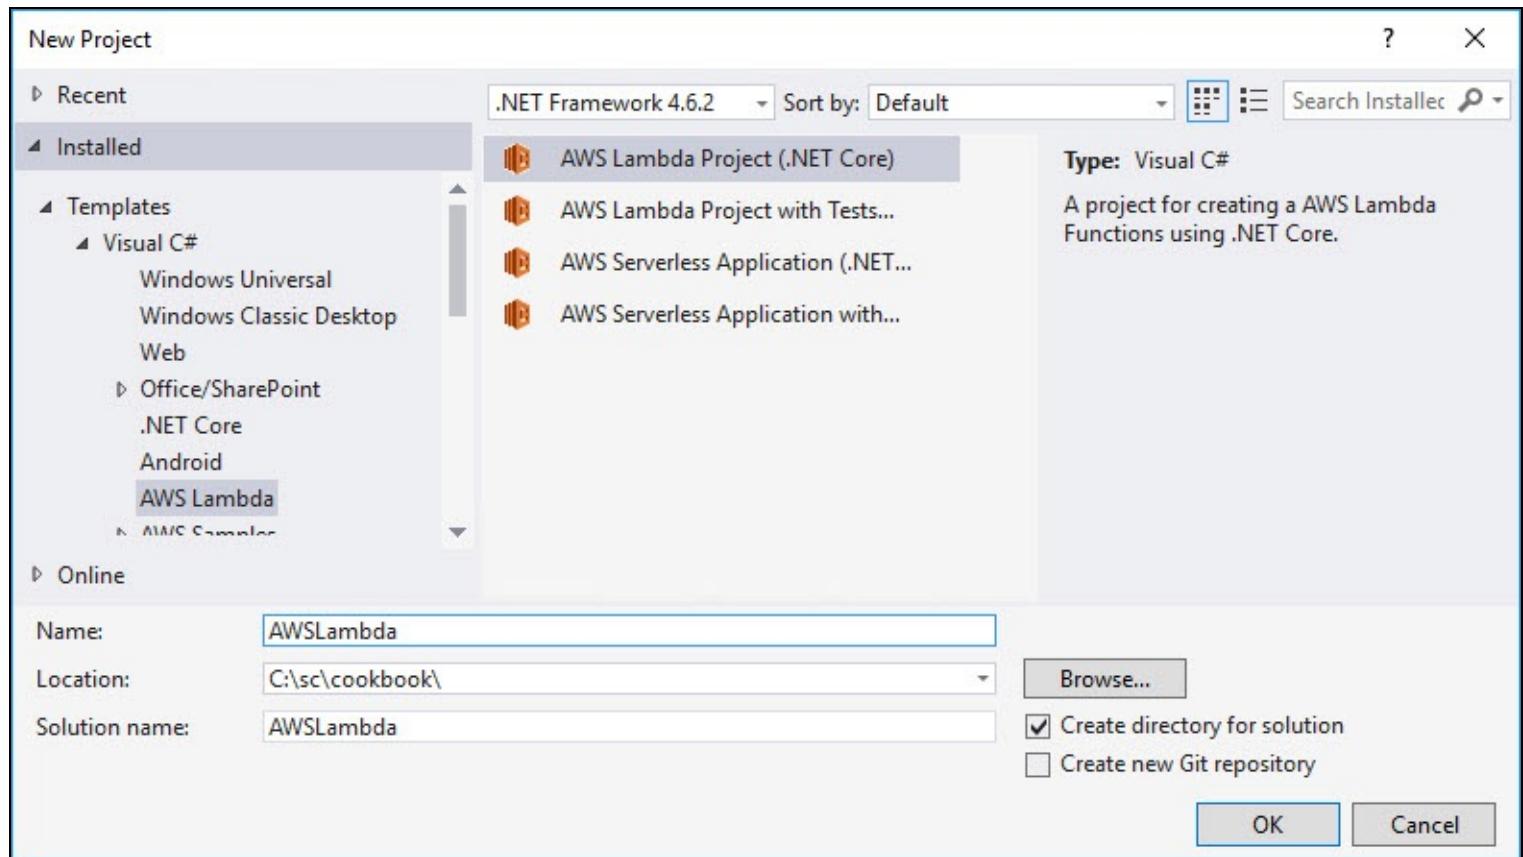

You need to ensure that you have downloaded and installed the preview of the AWS Toolkit for Visual Studio 2017. At the time of this writing, the toolkit could be found at this link: <https://aws.amazon.com/blogs/developer/preview-of-the-aws-toolkit-for-visual-studio-2017/>.

If you are using an earlier version of Visual Studio, download the AWS Toolkit from this link: <https://aws.amazon.com/visualstudio/>. This version of the toolkit supports Visual Studio 2015 and also allows you to download legacy versions for Visual Studio 2010-2012 and Visual Studio 2008. After you have downloaded and installed the toolkit, you are ready to create your first AWS Lambda function.

# How to do it...

1. Launch Visual Studio and create a new project. Under the Visual C# templates, you will see a new type called AWS Lambda. Click on the AWS Lambda Project (.NET Core) template. That's right, these are .NET Core apps.

2. The next screen will allow us to select a blueprint. For our purposes, we will just select a Simple S3 Function blueprint that responds to S3 event notifications.

## Select Blueprint

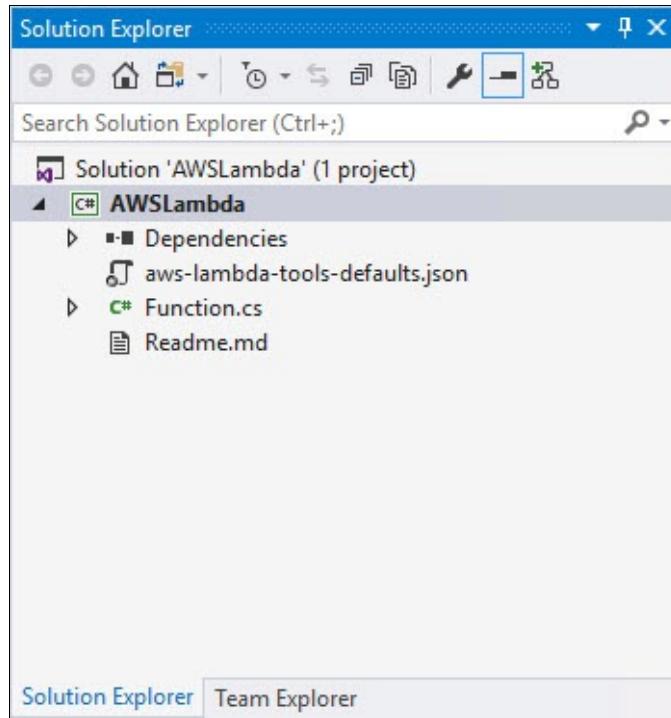

Choose the contents of the C# project for your AWS Lambda function.

Blueprints are Lambda projects that contain getting started code for your functions and a test project. Choose a blueprint that best aligns with your desired scenario and customize as needed.

Filter:

<b>Empty Function</b> Setup the project and test project to create a Lambda function from scratch.  <i>Custom</i>	<b>Detect Image Labels</b> Use Amazon Rekognition service to tag image files in S3 with detected labels.  <i>S3, Rekognition</i>	<b>Simple DynamoDB Function</b> A skeleton Lambda function to get started responding to Amazon DynamoDB stream events  <i>DynamoDB, Simple</i>
<b>Simple Kinesis Function</b> A skeleton Lambda function to get started responding to Amazon Kinesis events  <i>Kinesis, Simple</i>	<b>Simple S3 Function</b> A project for responding to S3 Event notifications  <i>S3, Simple</i>	

3. The function is created and your Solution Explorer in Visual Studio will look as follows.

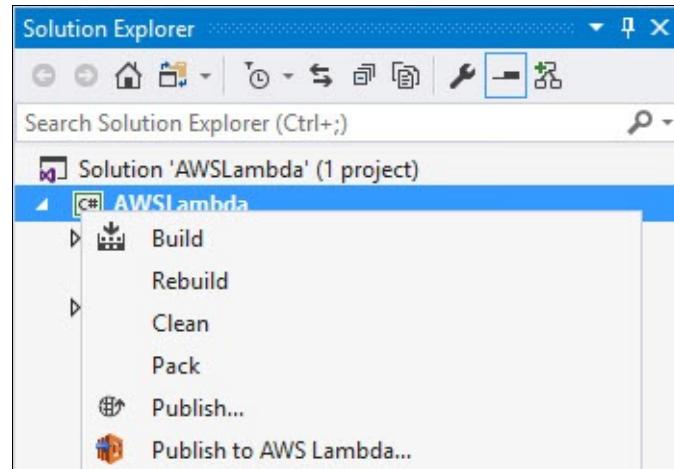

4. The code that is added to the `Function.cs` file is simply a class that has at its heart a method called `FunctionHandler()`. You will also notice an assembly attribute at the top of the class as follows:  
`[assembly: LambdaSerializerAttribute(typeof(Amazon.Lambda.Serialization.Json.JsonSerializer))]`. This is required

and registers the Lambda JSON serializer that is using `Newtonsoft.Json` to create our typed class. Since this code just works, I will not spend much time on explaining it.

```
public async Task<string> FunctionHandler(S3Event evnt,
                                         ILambdaContext context)
{
    var s3Event = evnt.Records?[0].S3;
    if(s3Event == null)
    {
        return null;
    }

    try
    {
        var response = await this.S3Client.GetObjectMetadataAsync
            (s3Event.Bucket.Name, s3Event.Object.Key);
        return response.Headers.ContentType;
    }
    catch(Exception e)
    {
        context.Logger.LogLine($"Error getting object
            {s3Event.Object.Key} from bucket {s3Event.Bucket.Name}.
            Make sure they exist and your bucket is in the same
            region as this function.");
        context.Logger.LogLine(e.Message);
        context.Logger.LogLine(e.StackTrace);
        throw;
    }
}
```

5. You can now publish the function to AWS directly from within Visual Studio. Right-click on the project that you created and from the context menu, select Publish to AWS Lambda....

6. You now need to complete the deployment wizard. Give your function a name, and if you do not have an account profile selected, add one.

# Upload Lambda Function

Enter the details about the function you want to upload.

## Profile

Account profile to use:  Region:

Language Runtime:

## Function Details

Function Name:

Configuration:  Framework:

Assembly Name:

Type Name:

Method Name:

*The Lambda handler field for .NET functions is <assembly>::<type>::<method>. The handler field indicates to Lambda the .NET code to call for each invocation.*

Save settings to aws-lambda-tools-defaults.json for future deployments.

*For your AWS Lambda function, be sure to select the same region as that of your S3 bucket c  
the previous recipe.*

7. Adding an account profile is really easy. This is the account you configured in IAM.

Profile Name:

*A profile name of 'default' allows the SDK to find credentials when no explicit profile name is specified in your code or application configuration settings.*

Access Key ID:

Secret Access Key:

Account Number\*:

Account Type:

Account information can be found at: <http://aws.amazon.com/developers/access-keys/>

\* Account Number is an optional field used for constructing Amazon Resource Names (ARN).

8. Clicking next will allow you to select the IAM Role Name that provides access permissions to S3 and our function. This is configured in the **IAM (Identity and Access Management)**.

Upload to AWS Lambda

## Advanced Function Details

Configure additional settings for your function.

**Permissions**

You can provide an IAM role for your code with appropriate permissions. For example, if your code needs to write to S3, the role you provide must have write permissions to S3.

Role Name: Existing role: PowerUserAccess

**Execution**

Memory (MB): 256

Timeout (Secs): 30 (1 - 300)

**VPC**

If your function accesses resources in a VPC, select the list of subnets and security group IDs (these must belong to the same VPC).

VPC Subnets:

Security Groups:

**Environment**

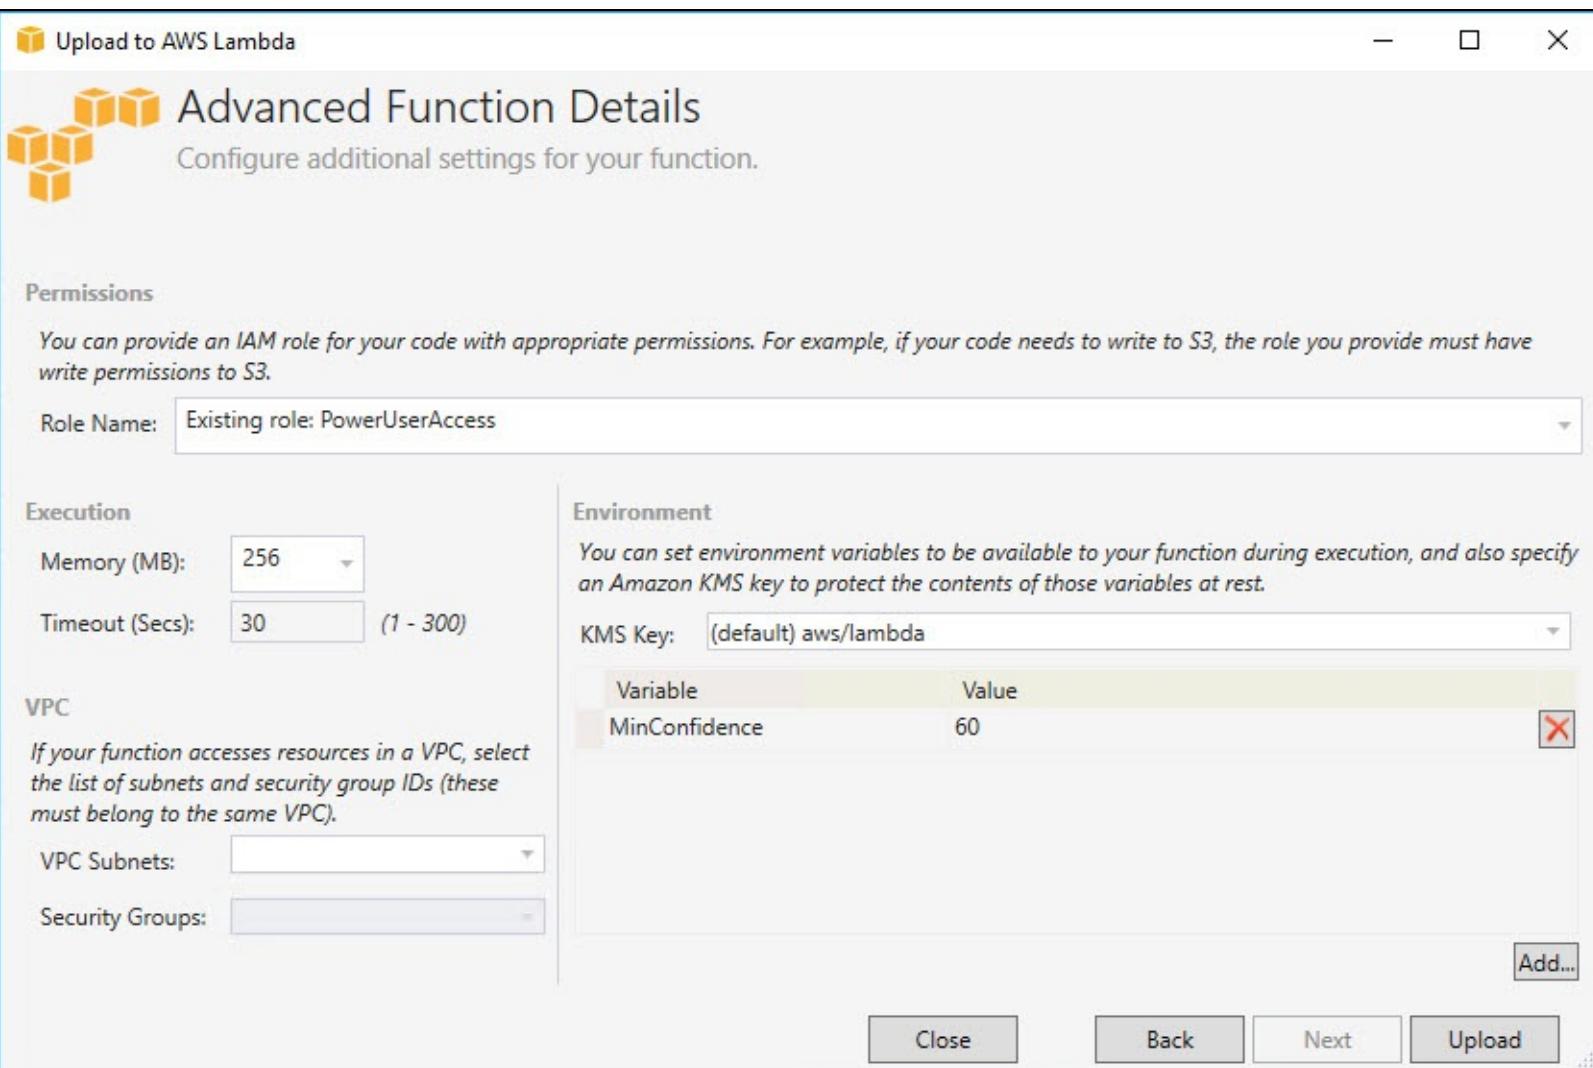

You can set environment variables to be available to your function during execution, and also specify an Amazon KMS key to protect the contents of those variables at rest.

KMS Key: (default) aws/lambda

Variable	Value	X
MinConfidence	60	X

Add...

Close Back Next Upload

9. Click on Upload to upload the function to AWS.

## Uploading Function

Please wait while we upload your function to AWS Lambda.

Open Lambda Function view after upload complete.

Automatically close wizard on successful completion.

[Close](#)

[Back](#)

[Next](#)

[Upload](#)

10. Take note, however, that there might be several permission issues encountered at this step. You might encounter something like the following:

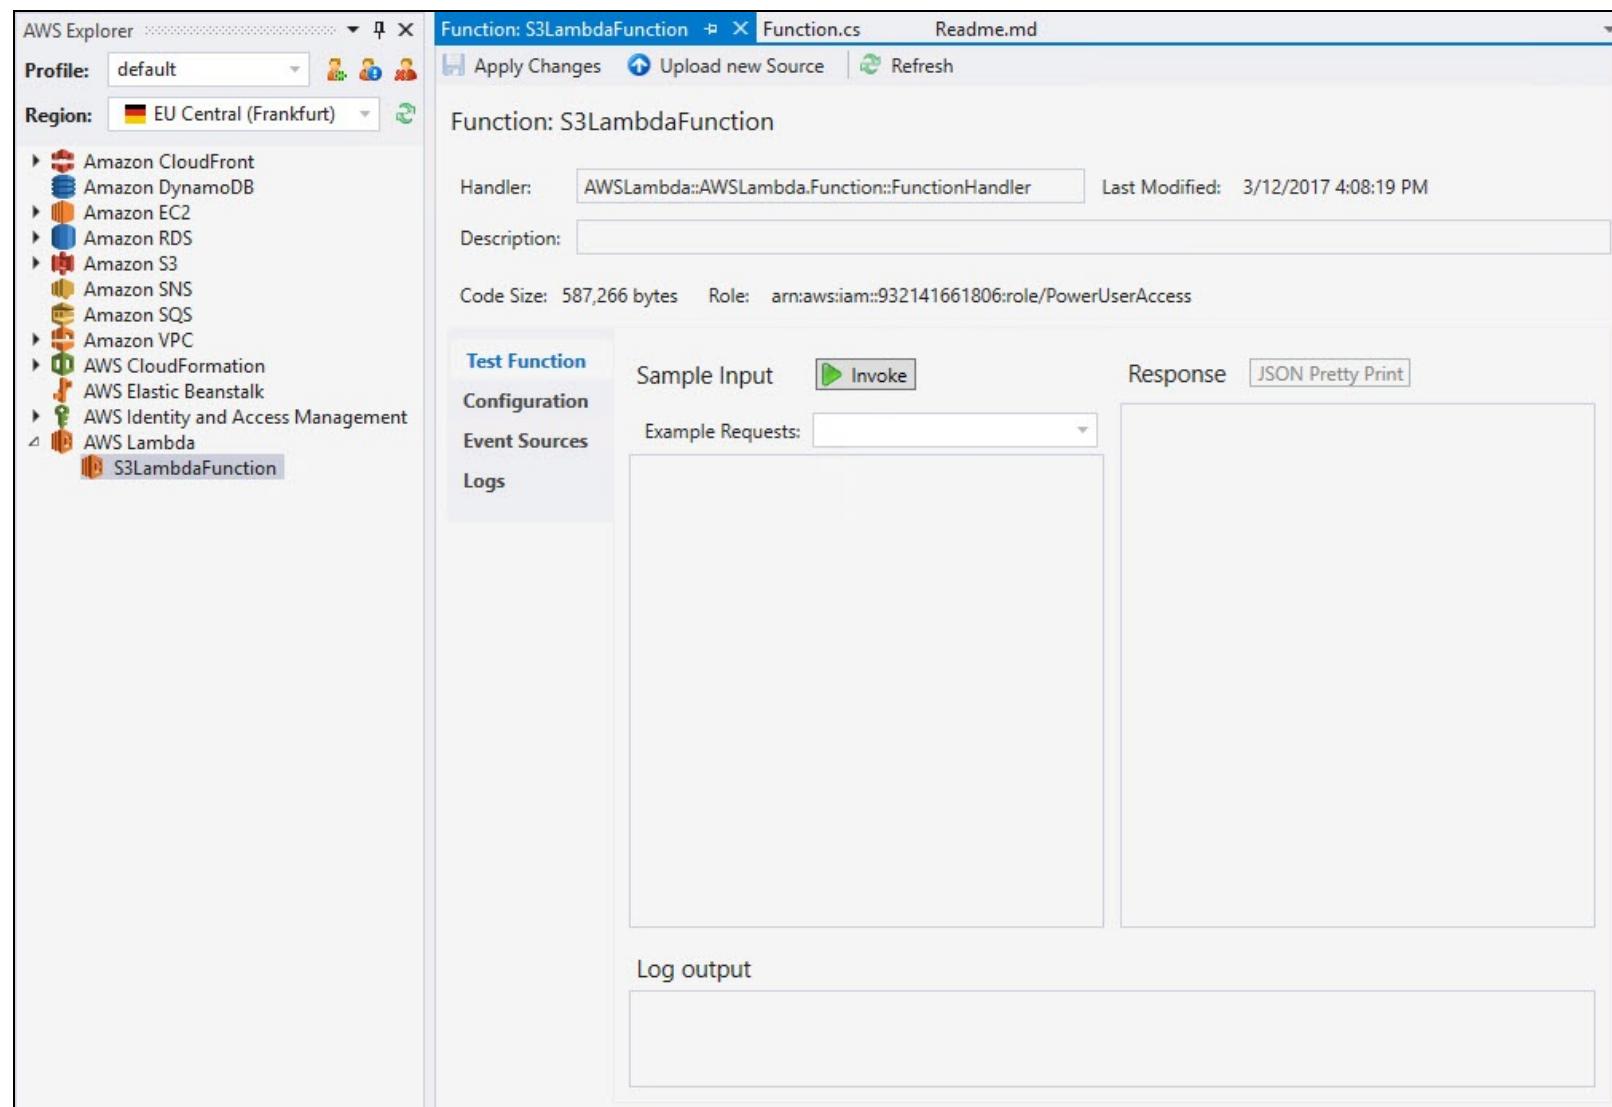

| Error creating Lambda function: User: arn:aws:iam::932141661806:user/S3Lambda is not authorized to perform: lambda:createFunction

You can in fact receive several such errors when trying to upload your function to AWS. The Identity and Access Management area in AWS is your friend here. You should have a look at the user you are using (in this case the user is S3Lambda) and review the permissions attributed to the user. Here, the error is informing us that the user S3Lambda does not have permission to create the function on AWS for the S3LambdaFunction resource. Modify your permissions and try uploading again.

# How it works...

After you have uploaded your function to AWS, click on the View menu in Visual Studio and select the AWS Explorer. Expanding the AWS Lambda node will show us the function we previously uploaded. If you see an error when expanding the node, you might need to give your user the ListFunctions permission. Expanding the AWS Identity and Access Management node will also show you the users, groups and roles you have configured. You can easily test your AWS Lambda function from within Visual Studio here by selecting one of the Example Requests and clicking on the Invoke button.

What we want to do, however, is hook up our S3 that stores files to send events to our function. Click on the Event Sources tab and click the Add button. Select Amazon S3 as the Source Type and select the `familyvaultdocs` bucket we created in the previous recipe. When you are done, click on the OK button.

While this example is not too complicated (with the exception of the permission settings perhaps), it does illustrate the concept of AWS Lambda functions. We can use the function to do a host of actions when triggered from something as simple as an event in an S3 bucket. Start to combine functionality and you can create a very powerful, serverless module to support and enhance your applications.

It does not matter if you are using AWS, Azure or something such as DocRaptor (or any of the other 3rd party services available). Serverless computing is here to stay and C# Lambda functions will change the face of development in a big way.
